Faba bean is partially allogamous. Breeders create synthetic faba bean cvs. usually by mixing inbred lines ("Syn-0"). After three generations of partial allogamous reproduction, the inbreeding coefficient F is reduced to ~minimum, i.e. the Panmictic Index (=1-F) has increased; seed is sold to farmers. This approach is **bottom-up** (**Fig.1**). Here, we present algebra and results from simulations to predict performance in **bottom-up** Syn-1 using data on yield (Y; *per se*, GCA) and on cross-fertilization X and paternal outcrossing success P of the inbred lines (components of synthetic).

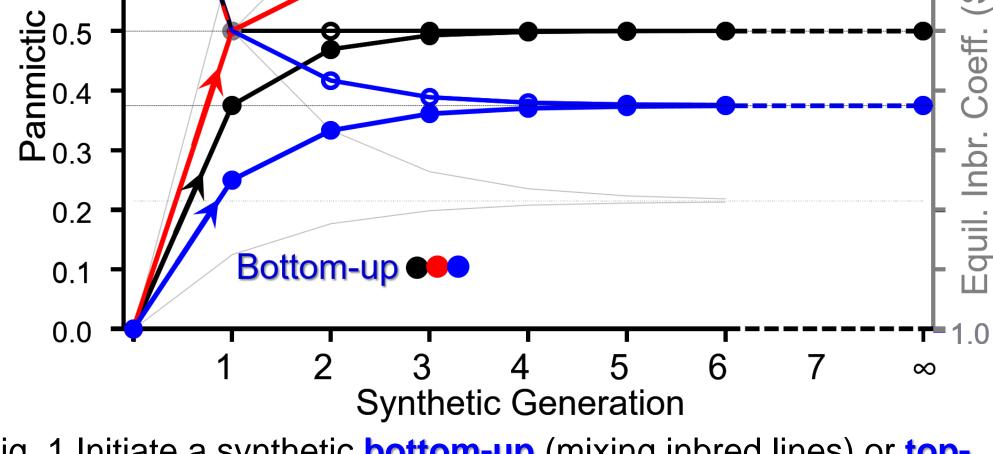

Fig. 1 Initiate a synthetic **bottom-up** (mixing inbred lines) or **top-down** (mixing F_2 from manually crossed F_1); to guarantee equal share contributions of the components to the synthetic cultivar)

Algebraic decomposition of performance in generation Syn-1, showing its dependence on parameters of components (inbreds); used to study the individual parameters' importance in the prediction of **bottom-up** Syn-1*

$$\mu_{\rm L} + \mu_{\rm X} \left(1 - \frac{1}{N}\right) \left(\mu_{\rm C} - \mu_{\rm L}\right) +$$

$$\frac{1/N \sum_{i=1}^{N} [(\mu_{X} + X_{i}) P_{ii}]\mu_{L} + 1/N \sum_{i=1}^{N} [1 - \mu_{X}(1 - \frac{1}{N})]L_{i}}{1/N \sum_{i=1}^{N} [(\mu_{X} + X_{i}) P_{ii}]L_{i} + \frac{1}{N} \sum_{i=1}^{N} \mu_{X} [(1 - \frac{1}{N})(2 \text{ GCA}_{i})] + \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (\text{GCA}_{j}) - \frac{1}{N} \sum_{i=1}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \text{GCA}_{i} - \mu_{L} - L_{i}) + 1/N^{2} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N}) (\mu_{C} + \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N} \sum_{\substack{i=1 \ i \neq j}}^{N} [X_{i} (1 - \frac{1}{N}$$

 $1/N \sum_{i,j=1}^{N} [(\mu_{\mathbf{X}} + X_i) \mathbf{P}_{ij} (\mu_{\mathbf{C}} + \mathbf{GCA}_i + \mathbf{GCA}_j)]$

*L=per se yield of inbred lines; C=F1-hybrid yield; X=degree of cross-fertilization;

Bottom-up (A): Prediction of Syn-1 is not perfect, because differences between lines for *per se* yield, GCA for yield, degree of cross-fertilization X, paternal outcrossing success P are realized.

Top-down (**B**): Prediction of Syn-1 (i.e. mixture of F_2) is perfect. Prediction of Syn- ∞ (**C**) is a different ball game and can only be executed **top-down**. Components (usually 2<N<8) differ *e.g.* in X and P. Thus, their genetic share in generation Syn-1 ff. deviate from 1/N; hence the panmictic index of the *cv.* is lowered and less heterosis exploited. To prevent this, the synthetic may be initiated with e.g. 6 crosses among N=4 lines. Then, create and mix F_2 s of these crosses in equal shares. This F_2 mixture is the **top-down** Syn-1 (Fig.1). Further propagation leads to a panmictic index in Syn-4 similar to **bottom up**.

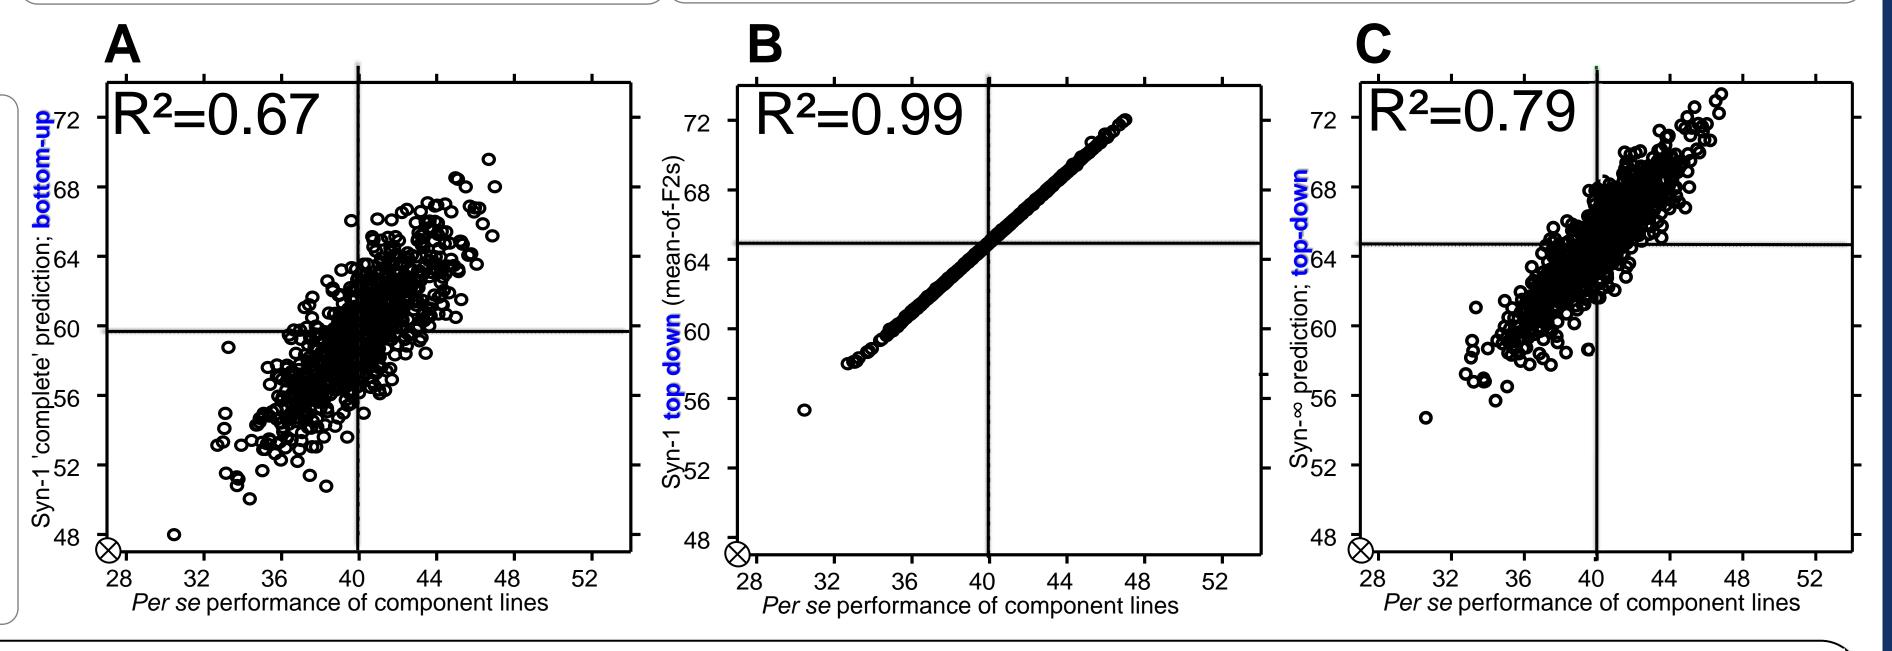

Breeders predict yield of **bottom-up** created synthetics in Syn-1 via *per* se yield of their inbred components. What is the impact of knowing *per* se yield, GCA for yield, X, P, when predicting? N=4 component inbred lines per synthetic

Parameters		Expl. Var (%)
Per se or GCA as only parameter for pred. of Syn-1		67.00
Degree of cross-	Added to per se, GCA, P for prediction	21.90
fertilization X	As only parameter for prediction	25.09
Paternal outcros-	Added to per se, GCA, X for prediction	11.10
sing success P	As only parameter for prediction	14.69

N=4 components in Syn-0; *per se*=per se yield of inbred lines, GCA=their general combining ability for yield, X=their degree of cross-fertilization, P=their paternal outcrossing success (success when siring others)

P=paternal outcrossing success (success when siring others)

bottom-up synthetics in generation Sy Parameter	/n-1 and Syn- Mean	-∞ Standard Deviation
Degree of cross-fertilization	50.0%	8.0%
Paternal outcrossing success* N=4	25.0%	8.6%
Per se yield of inbred lines	40 dt ha ⁻¹	5.0 dt ha ⁻¹
GCA (yield) of inbred lines	2.5 dt ha ⁻¹	2.5 dt ha ⁻¹
SCA for pairs of inbred lines	0.0 dt ha ⁻¹	0.0 dt ha ⁻¹
Yield of F1-hybrids	90 dt ha ⁻¹	7.1 dt ha ⁻¹
*based on data from literature, e.g. Bri	injes et al., 2	021
(DOI 10.1007/S00122-021-03832-z)	-	

Per se yield of inbred components explained 67% of variance between faba bean synthetics in bottom-up Syn-1 (N=4). Adding data on components' degree of cross-fertilization X allows to explain 67.0%+21.9%=88.9%; then-adding data on P explained 100%. Top-down allows to better (99 % > 67%) predict Syn-1 from *per se* yield. Approaching the cultivar's equilibrium inbreeding coefficient (i.e. max. heterosis exploitation) is faster with top-down (given 33% < X < 67%). Increase in heterosis exploitation with top-down (compared to bottom-up) is very small.

With 3200 simulated candidate inbreds and N=4 inbred components per synthetic, a large number of different synthetics can be created: $(3200 \cdot 3199 \cdot 3198 \cdot 3197)/(4!) \approx 4.361 \cdot 10^{12}$. We did not simulate them all but only 800 (taking 800 random, non-overlapping sets of four; 3200=800·4).

Breeders prefer to 'just' mix seed of superior inbreds (Syn-0) and let such mixture propagate to Syn-1 and beyond. With partial allogamy, such synthetic reaches its inbreeding equilibrium (= inbreeding minimum) in about Syn-4. At about Syn-4, seed is sold to farmers. This is the **bottom-up** approach - as the inbreeding minimum is approached from the 'bottom' (depth) of inbreeding. Yet. **Bottom-up** causes <u>deviations</u> of the cultivar from <u>expectation</u>, which is based on the inbreds' *per se* yield, average level of heterosis (& maybe on degree of cross-fertilization of the inbreds); and on their number N. **Bottom-up** allows the components to genetically contribute <u>unequally</u> to their synthetic. Components with more seeds per plant in Syn-0 contribute a higher share than 1/N to their Syn-1. Further, components with the higher degree of cross-fertilization X in Syn-0 contribute a genetic share <1/N, because a larger share of their seeds carries their genes only *via* maternal gamete. Even further, on the paternal side, the components with higher paternal outcrossing success P contribute more than 1/N. Unequal contributions reduce the population's effective size, hence increase inbreeding, hence decrease share of heterosis: <u>decrease vigour</u>.

How important are unequal genetic shares? Let's take one extreme scenario for N=4: two components have X=0% and two components have X=100%. This causes deviation from 'eachcontributes 1/4': now 'two-give 5/16' (X=0%) and 'two-give 3/16' (X=100%). The average Panmictic Index of out-crossed individuals in such population (Syn-1 onwards) is less than (N-1)/N=0.750, it is 0.7344. For the synthetic, this means an approximate reduction of is equilibrium Panmictic Index from 0.50 down to 0.4895. Admittedly, a very small loss.

While we're at it ;-) ... breeders may intentionally create synthetics with unequal share. Take N=4 and let the components deviate from 25% by amounts a,b,c,d per component. For example, create the Syn-0 with 100 seed of each of three inbreds but add 700 seed from the fourth component; hence contributions are 10%, 10%, 10%, 70% (deviations from 25% are a,b,c=15% and d=45%). The resulting increase in inbreeding, Δ F, of the outcrossed individuals of that population is: Δ F = (a+b+c)²+a²+b²+c² (here, Δ F=0.52, an increase from F=0.25 to F=0.77; a marked loss of the heterotic potential). For the entire synthetic, this means a reduction of its average Panmictic Index from 0.50 down to 0.15 – this now is a marked loss.

With N=4, randomly occurring associations between X and *per se* yield (and GCA) have to be expected. In our basic pool of the simulated 3200 lines, that correlation was r=0.00, yet, it is r>0 in a typical quartet of components (initiating any of our 800 synthetics). In most Syn-0, there was a negative or a positive correlation, the mean absolute value was r=0.494. This association is the reason for the improvement of the prediction of **bottom-up** Syn-1, if X of the individual component is considered (in addition to *per se* yield). Such association is almost resolved with the **top-down** approach, especially if you realize all six possible cross-combinations and if yield loci are unlinked with loci for reproductive behaviour. *Nota bene*: The predicttion of the **bottom-up** Syn-1 beyond Syn-1, for Syn-4 or Syn-∞, is a different game, and R² (using *per se* performance) would be rather ~0.60 than 0.67. And: If you select among components based on their ~polycross-progeny-test instead of their yield *per se* data, you are closer to **bottom-up** – this approach was

An alternative to improve the situation is the **top-down** approach: Manually cross the components to prevent unequal contributions! Here, the inbreeding equilibrium is approached **top-down** (from the 'peak' of heterozygosity). With N=4, one can realize 2 or 4 or 6 crosses to have equal-share of the 4 components. From these F_1 , produce F_2 and mix them (no selection; called **top-down** Syn-1). Interestingly, the Panmictic Index in F_2 is - accidentally - identical to the equilibrium Panmictic Index in Syn- ∞ (if X=50% and N=4; realistic values in faba bean). Message: With X=50% and N=4, the **top-down** Syn-1 (F_2 -mixture) already arrived at its inbreeding minimum. Moreover: With 33% < X < 67% and N=4, **top-down** approaches the inbreeding equilibrium faster (is nearer to it in *e.g.* Syn-4) than **bottom-up** ;-)

indeed be formulated! This is not the case for the **bottom-up** Syn-∞; because with **bottom-up**, the components 'themselves' are still in some frequency present in Syn-1 and beyond and still influence composition and average inbreeding coefficient of subsequent generations.

Although variation in X between components in **bottom-up** Syn-0 causes no marked impact on heterosis exploitation, nevertheless: Ignoring differences in X between components leaves ~21.9% of variation between **bottom-up** Syn-1 unexplained. Unequal shares are caused by coincidental combinations of *e.g.* high (or low) *per* se yield and high (or low) X of a component in **bottom-up** Syn-0.

not studied here.

If the *per se* yield was considered, GCA was implicitly considered, because the correlation between *per se* yield and GCA for yield was assumed as r=1 (Quantitative Genetic expectation in case of no epistasis and degree of dominance $0 \le d/a \le 1$).

Further assumptions to be mentioned: No genetic differences in fitness, i.e. no differences in seed numbers per plant. No heterosis for X. Linear relationship between inbreeding coefficient and yield heterosis. No contamination in Syn-0 and later with alien pollen. The mixture of the **top down** F_2 bulks was defined as Syn-<u>1</u> **top down**, thus equated with the Syn-generation of **bottom up** Syn-<u>1</u>.

Breeders may argue in favour of **bottom-up** for reasons of easier feasibility; no need to manually cross. Yet, in faba bean, propagation of inbreds *via* controlled selfing involves a certain effort, not much different from selfing F_1 to get F_2 . Often, line breeding precedes synthetic breeding, hence, crosses and F_2 may be ready-at-hand. Besides, lately breeders dispose on highly homozygous individuals to be used for Genomic Selection, hence ready for crossing - but not ready for field testing (because not propagated yet).

This methodological discussion seems to not yet be finished.
