Photo 173. Panorama photograph taken from the orographic right valley flank of the Bote Koshi Drangka WNW above the Thame-Teng alpine pasture at 4550 m a.s.l. (Figure 3 Panorama 173) from facing N (left margin) along the orographic right valley flank up the Bote Koshi Drangka on to the 7552 m-high Nangqi Gosaum (No. 5) up to facing NNE with the 8302 m-high Cho Oyu (No. 4) and the 5941 m-high (No. 72) situated 15 km nearer, into the orographic left flank of the Bote Koshi (right margin). On the valley flanks ground moraine covers (Ⅳ) are preserved up to altitudes of 4900 m a.s.l. (up to above black on the right). (IV) marks late Lateglacial remnants of ground moraine pedestals (terraces of pedestal moraines) of the Sirkung-Stage (Table 1), the terraces of which (IV black, bold) reach altitudes of 400–500 m above the valley bottom. (IV vertically below No. 4) is the sampling locality of sample 30.3.03/1 (Figure 77; Figure 37 No. 34). (V) are the tongue basins and end moraines of late-glacial side- and hanging glacier tongues of the Nauri-Stage, adjusted to this terrace of pedestal moraine. (VII) are end moraines of the middle Dhaulagiri-Stage. (Ⅳ) are gullies which since the Lateglacial deglaciation have been cut into the decametres-thick ground moraine pedestal. (Ⅰ) is a debris cone as a corresponding full-form. (Ⅳ) is a classic, glacigenically triangle-shaped slope face developed from a truncated spur polished back by the Ice Age Bote Koshi glacier (Figure 3 on the left of No. 91 Ⅳ). (Ⅳ) are glacigenic flank abrasions which together with the truncated spur indicate the Würmian glacier trim-line at 5900 m (on the left of No. 72) up to 5500 m a.s.l. (on the right of No. 72) and further down-valley about 5300 m (Figure 34) to 5100 m a.s.l. (on the right). Analogue photo M. Kuhle, 5/4/2003.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 172. 330° panorama taken at 4920 m a.s.l. from the orographic left valley flank of the Bote Koshi Drangka E above the Arye alpine pasture (Figure 3 Panorama 172) from facing NNW (left margin) with the orographic left hanging side valley of the Bote Koshi, via facing WSW into its left flank with the 5940 m-peak (No. 98; Table 5), facing SW with the 5915 m-peak (No. 91) situated 2.7 km to the left, via facing S down the main valley on to the 6457 m-high Kongde Ri (No. 60), via facing WSW into the orographic right flank of the Bote Koshi with the 5967 m-peak (No. 99), via facing WNW on to the 6423 m-peak (No. 98) and the 6705 m-high Kang Korob (No. 80), then up the Chhule Drangka facing NW with the summits of Pangbug Ri (No. 78, 6716 m) and the 6589 m-peak (No. 96) up to facing N (right margin) across the orographic left main valley flank. (IV) is the more than 500 m-high pediment moraine terrace and its down-valley remnants of the Sirkung Stage (Table 1); (V and VI) are local neoglacial lateral- and end moraines in the Bote Koshi side- and main valley originating from the Nauri- and older Dhaulagiri-Stage (Table 1); there are also (VI) frontal moraines of local hanging- and cirque glaciers. (h) shows remnants of ground moraine covers in high positions at 4500 m (below No. 80), 4850 m (below No. 85), 5000–5300 m (below Nos. 90, 95 and 78), (n) is a very clear, triangle-shaped glacigenic slope face developed from a truncated spur (Figure 3 above No. 89). (n) are glacigenic flank abrasions in the bedrock gneiss indicated by rock roundings. (...) is the High Würmian glacier trim-line, running about 5500 m a.s.l. (... right and left margin up to left of No. 90) above the hanging side valley, down to ca. 5500 m a.s.l. in this section of the main valley (... below No. 90 up to left below 89) (Figure 34). Up the main valley (... below No. 90 and 94) its altitude was ca. 5800 m a.s.l. Analogue photo M. Kuhle, 30/3/2003.
Photo 175. Picture taken from the orographic left valley side of the upper Bote Koshi Drangka between the Arye and Chhule alpine pastures at ca. 4450 m a.s.l. (Figure 3) Photo 175: on the ground moraine in the neoglacial tongue basin of the Nauri Stage (V, Table 1); perfectly rounded granite gravels with aperox, the form of a ball (diameter of the lens cap on the right above ~9 cm). Analogue photo M. Kuhle, 02/04/2003.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 174. 360°-panorama photo taken at 4380 m a.s.l. from the orographic left valley side of the Bote Koshi Drangka from the Arye alpine pasture down-valley in a S-direction (Figure 3 Panorama 174) from facing NNW (left margin) up the trough valley (Figure 34) to the 5719 m-peak (No. 75), via facing W into the orographic left valley flank to the 5949 m-peak (No. 90), via WSW and SW with the 6186 m-high Kyajo Ri (No. 68) and the 5930 m-peak (No. 91), via facing SW down-valley (Figure 31) with the 6187 m-high Kongde Ri (No. 60), via facing W into the orographic right valley flank with the 5967 m-peak (No. 89) and again facing NNW (right margin). (\(n\)) are ground moraine covers, mainly preserved in the lower slope regions of both valley flanks. In many places they have been reshaped and overlain by debris flow cones and -fans (\(s\)). (\(s\)) are granitic, round-edged moraine boulders, dislocated by debris flows such as these. They have been transported out of a gully (\(s\)), which has been cut into a pedestal moraine terrace (IV) (Figure 3 Panoramas 171 and 172) of the Late Glacial Sirkung Stage (Table 1). (\(h\)) is the gravel bed of the current Bote Koshi river, incised as talweg into the ground moraine of the valley bottom. (\(\dot{h}\)) shows an E-exposed sinuosity-like form (Figure 3 on the right of No. 89). It has been reworked for the last time by a Late Glacial hanging glacier. (\(\dot{\dot{h}}\), \(\dot{\dot{\dot{h}}}\)) are glacigenic forms of flank abrasion, i.e. rock smoothings and -roundings. (\(\dot{h}\)) is a very well preserved, classic, glacigenically triangle-shaped slope area derived from a truncated spur, which has been polished back by the Ice Age Bote Koshi glacier (Figure 3 on the left of No. 68). (...) are High Würmian glacier trim-lines (Stage 0, Table 1) verified by abrasion lines: (...) on the very left and very right run about 6000–5900 m a.s.l., (...) on the right of No. 75 about 5800 m, (...) below Nos. 90 and 68 as well as on the left of No. 89 and on the right of No. 60 about 5700 m, (...) on the left of No. 60 about 5200 m a.s.l. Analogue photo M. Kuhle, 28/03/2003.

Photo 176. Panorama photo taken at 4360 m a.s.l. from the orographic left valley flank of the Bote Koshi Drangka down-valley from the Lungare settlement in a NW-direction (Figure 3 Panorama 176) from facing WNW (left margin) with the right valley flank, via facing NNW up-valley to the 5719 m-peak (No. 75), up to facing ENE to the 5949 m-peak (No. 90) in the orographic left valley flank. (\(n\)) are ground moraine covers and deposits with a thickness of up to 200 m (\(n\), white) (Figure 34); the latter are Late Glacial remnants of a ground moraine pedestal (IV, Figure 3 Panorama 171 and on the right below Panorama 174). (\(s\)) are alluvial- and debris flow fans of dislocated ground moraine, which have been adjusted to the surfaces of ground moraine and accumulated. (\(\dot{\dot{h}}\)) are rounded and edged granite- and gneiss boulders metres in size, which are typical of moraine. (For scale see below of (\(h\)).) A small expedition caravan with five persons and two loaded Sobjoks (Zuus). (\(h\)) is the gravel bed of the current Bote Koshi river, which during the Holocene – along with its vertical erosion as a fluvial gravel floor – has been set into the ground moraine. (\(\dot{h}\)) is a convex rounding of the rock flank by glacigenic flank abrasion. (...) indicates the High Würmian glacier level in the upper Bote Koshi about 6000–5900 m a.s.l., (---) is the one further down-valley about 5800 m a.s.l. Analogue photo M. Kuhle, 28/03/2003.

(IV large, foreground on the left) are remnants of the Late Glacial ground moraine pedestal, which has filled the Bote Koshi. (IV large, foreground on the left) are remnants of the Late Glacial ground moraine pedestal, which has filled the Bote Koshi.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

--- Photo 179. Picture at 4390 m from the orographic right valley flank of the middle Botekoshi Drangka in the area where the Langmoche Drangka joins (Figure 3). It is a completely preserved glacigenically triangle-shaped remnant of the Late Glacial ground moraine pedestal (IV) facing NW to the 5080 m ridge (Figure 3). (a) is the Würmian minimum ice level between 5000 to 5200 m a.s.l. at this locality indicated by this glacial erosive form. (b) is a gneiss boulder the size of a hut (cf. person on the right) situated ca. 100 m away from the slope foot. Its material does not outcrop on the triangular-shaped slope behind it. Accordingly, this is an erratic moraine boulder 400 m above the talweg on this cross-profile of the Botekoshi (Figure 3). Analogue photo M. Kuhle, 27/03/2003.

--- Photo 180. At 4380 m a.s.l., picture taken from the orographic left valley flank of the lower Langmoche Drangka in the area where it join the middle Botekoshi Drangka (Figure 3). It is a triangle-shaped remnant of the Late Glacial ground moraine pedestal (IV) facing SE down the main valley to the 6369 m high Kusum Kanguru (No. 73). This erratic augen-gneiss boulder (c) is situated 400 m above the talweg of the Botekoshi (yellow line on the left margin). Weathering has shaped it into an extremely angular and rough form and surface. (d) are High Würmian to Late Glacial remnants of ground moraine near to the valley bottom, in part modified by postglacial debrisbodies down the slope (f). (g) are glacigenically back-polished rock spurs. (h) is a channel caused by current avalanche- or rock fall, from which these forms of debris cones emerge in a downslope direction. (i), (j) are past glacigenic flank roundings and -abrasions, the upper limit of which indicates the Würmian glacier trim-line (...). It runs from approx. 4400 m (... half-left below No. 73) and on the very right, Figure 36 down to 4000 m a.s.l. (the two ... on the right below No. 73; Figure 52). (k) white) is a classic glacial band polishing of the outcropping edges of the stratum (‘Schichtkopfstreifenschliff’ after v. Klebelsberg, 1948/49) on the outcropping gneiss banks. (l) are two orographic right lateral moraines of the neoglacial Nauri-Stage (Table 1), approximately parallel in arrangement, at the exit of the Langmoche (V below) and the Arabtsen Drangka. (m) is a slide of the inner moraine slope of the lateral moraine at the valley exit of Langmoche, triggered by an outburst of a moraine lake (Dig Tsho) in 1985. (n) small) show two further slides of slopes in the loose rock near to the valley bottom caused by this event. Analogue photo M. Kuhle, 27/03/2003.
Figure 3 shows the orographic left valley flank of the lower Langmoche Drangka in the area of its inflow into the middle Bote Koshi Drangka at 4900 m a.s.l. (Figure 3 Photo 181) taken from facing ENE (left margin) via facing E with the 5583 m-high Kabsale (No. 92) in the left flank of the Bote Koshi Drangka, via facing SE down the Nangpo Tsangpo Drangka to the 6369 m-high Kusum Kanguru (No. 73), facing SSE to the 6187 m-high Kongde Ri (No. 20) and facing SW into the right flank of the tributary valley to the 6180 m-peak (No. 88), facing W to Tangi Ragi Tau (6940 m, No. 83), via facing WNW to the 5890 m-pass (No. 82), which leads to the Drolum Bau glacier (Figure 3) and the 6362 m-summit (No. 97), situated on the watershed to the W-adjacent Rolwaling Himal, up to facing NW to the 5080 m-high mountain spur between Langmoche- and Bote Koshi Drangka (5080 m-ridge Figure 35) (right margin). The round-edged and edged moraine boulders consist of banded gneiss, augen-gneiss and granite; they are erratic and have more or less been transported over a long distance. The rock slope covered with metre-thick ground moraine. (IV small) are late Late Glacial remnants of ground moraine of the Sirkung Stage (Table 1). A tongue basin of a hanging glacier of the neoglacial Nauri Stage (V) has been set into them during the Holocene (i.e. the High Würmian glacier level between ca. 4100 m (... below No. 83) and 5100 m a.s.l. (... left margin), verified by an upper abrasion limit (below No. 83) and two glacigenic polish cavettes (... below No. 88 and near the left margin). Obviously there was an ice transfluence (... on the right below No. 86; see Figure 3 transfluence pass half-left below Panorama 186) between the Langmoche- and the Arabtsen Drangka situated beyond. Analogue photo M. Kuhle, 27/03/2003.

---

Figure 4 shows the orographic left valley flank of the lower Langmoche Drangka in the area of its inflow into the middle Bote Koshi Drangka at 4900 m a.s.l. (Figure 3 Panorama 181) taken from facing E with the 5583 m-high Kabsale (No. 92) in the left flank of the Bote Koshi Drangka, via facing SE down the Nangpo Tsangpo Drangka to the 6069 m-high Kasum Kanguru (No. 73), facing S by the 6187 m-high Kongde Ri (No. 83) and facing SW into the right flank of the tributary valley to the 6180 m-peak (No. 88), via facing W to Tangi Ragi Tau (6940 m, No. 83), via facing WNW to the 5890 m-pass (No. 82), which leads to the Drolum Bau glacier (Figure 3) and the 6362 m-summit (No. 97), situated on the watershed to the W-adjacent Rolwaling Himal, up to facing NW to the 5080 m-high mountain spur between Langmoche- and Bote Koshi Drangka (5080 m-ridge Figure 35) (right margin). The round-edged and edged moraine boulders consist of banded gneiss, augen-gneiss and granite; they are erratic and have more or less been transported over a long distance. The rock slope covered with metre-thick ground moraine. (IV small) are late Late Glacial remnants of ground moraine of the Sirkung Stage (Table 1). A tongue basin of a hanging glacier of the neoglacial Nauri Stage (V) has been set into them during the Holocene (i.e. the High Würmian glacier level between ca. 4100 m (... below No. 83) and 5100 m a.s.l. (... left margin), verified by an upper abrasion limit (below No. 83) and two glacigenic polish cavettes (... below No. 88 and near the left margin). Obviously there was an ice transfluence (... on the right below No. 86; see Figure 3 transfluence pass half-left below Panorama 186) between the Langmoche- and the Arabtsen Drangka situated beyond. Analogue photo M. Kuhle, 27/03/2003.
Photo 184. Long-distance photo from the orographic right valley flank of the middle Bote Koshi Drangka below the inflow of the Langmoche Drangka at 4550 m a.s.l. (Figure 3 Photo 183) facing NNE up the Bote Koshi main valley. No. 4 is the 8202 m-high Cho Oyu, No. 72 the 5941 m-peak, No. 90 the 5490 m-peak. (IV) are late Late Glacial remnants of ground moraine of the Sirkung Stage (Table 1), which in many places (IV small) are preserved as terrace remnants. (●) are up to 3 m-long edged to round-edged moraine boulders of gneiss, among them far-travelled augen-gneiss. (●) are ground moraine remnants in the form of covers, verifiable up to 4000 m a.s.l. (●) below No. 90. (●) is the remnant of a ground moraine pedestal, superficially covered by an alluvial- and debris flow fan (Figure 3 on the left above Panorama 191) from dislocated ground moraine situated higher up. (V) is a neoglacial (Nauri Stage, Table 1) tongue basin of a Holocene hanging glacier, which has filled two poorly developed cirque steps (∙ and ∙; Figure 3 on the left diagonally below No. 68). The glacier has removed the High- to late Late Glacial accumulations of ground moraine, i.e., dug its tongue basin into them. (●) are glacigenically triangular-shaped slopes in the bedrock; (‡, ‡) are glacigenic abrasions in the form of rock smoothings and -roundings, in some places roughened by crumblings. (___) is the High Würmian glacier level at 6000 m a.s.l. (___ on the right below No. 4; cf. Figure 33), 5900 m a.s.l. (____ below No. 72) and 5500 m a.s.l. (____ on the left below No. 90; Figure 34). Analogue photo M. Kuhle, 05/04/2003.

Photo 185. Picture taken from the orographic right valley flank of the middle Bote Koshi Drangka above the inflow of the Langmoche Drangka at 4390 m a.s.l. (Figure 3 Photo 188) from the triangle-shaped large-scale terrace-remnant of the Late Glacial ground moraine pedestal (IV) facing NNE up the Bote Koshi Drangka. No. 4 is the 8202 m-high Cho Oyu, No. 72 the 5941 m-peak. (●) is a neoglacial front moraine of the Stages VI–VII (older and middle Dhaulagiri Stage, Table 1; see Figure 3 below No. 72 VI–VII). (●) are High Würmian (Stage 6) to Late Glacial (Stages I–IV) parts of a ground moraine cover, attached to the valley flanks. (○) is a gneiss boulder the size of a hut on the ground moraine cover. (--+), (+++) marks polished gneiss bedrock in a roche-moutonnée-like form, which has been roughened and damaged by rock crumblings since the deglaciation. Analogue photo M. Kuhle, 27/03/2003.
Photo 183. 390%C176-panorama from the orographic right valley flank of the lower Langmoche Drangka, i.e. the right valley flank of the main valley in the area where the Langmoche Drangka joins the middle Bote Koshi Drangka, taken at 4550 m a.s.l. (Figure 3 Panorama 183) from facing SSW (left margin) via facing SW with the 6180 m-peak (No. 88) in the background, facing W to the 6480 m-high Tang Ragi Tau (No. 89), via facing WNW to the 6532 m-peak (No. 96), via facing NW to the 6362 m-peak (No. 97), up to again facing SSW (right margin). This ground moraine remnant of the Sirkung Stage (Table 1) continues up the tributary valley (IV black, large) and up the main valley (IV small). It reaches up to 4400 m and consists of 1–3 m long, round-edged and edged polymict boulders of metamorphites, granite (››) and gneisses (››); the latter are erratic. (V black) is the tongue basin of a neoglacial (Nauri Stage V, Table 1) hanging glacier, which has flowed down from a cirque (¨) on the very left. It is covered with ground moraine. (V white) is the end moraine of the Langmoche glacier from the Nauri Stage; due to a slide its inner slope has crumbled away (to the right near V white). (The two further right) are transfluence passes between 5800 and 5950 m a.s.l. rounded by the overflowing High Wu¨rmian ice. (...) is the High Wu¨rmian level of the ice stream network between 6200 and 6000 m a.s.l. (...) below Nos. 83–104 and on the right below No. 4). It has dropped from the side valleys down to the main valley to 4000 m a.s.l. (...) below No. 73) practically without any intermediate steps. Analogue photo M. Kuhle, 05/04/2003.

Photo 187. Long-distance panorama from the orographic left valley flank of the middle Bote Koshi Drangka ENE above the Muraling settlement at 4725 m a.s.l. (Figure 3 Panorama 187) from facing SSW (left margin) with the 6959 m-summit Numbur (No. 93) and the summits of Teng Kangpoche (No. 87, 6500 m) and Panayo Tuppa (No. 86, 6696 m) in the crest in front of them, up to facing SW (right margin). (¢) are N-exposed cirques and similar forms in the intermediate valley ridge between Langmoche (background) and Auntion Drangka (below Nos. 87 and 86) again situated in front of it. (VII–X) show holocene to historic front moraines of a small hanging glacier of the middle Dhaulagiri Stage up to Stage X (Table 1, Figure 1 on the right of No. 88). (V) are the bottoms of the tongue basin of the Nauri Stage covered with ground moraine, the holocene hanging glaciers of which have cleared out part of the late Late Glacial accumulations of ground moraine (IV) (Sirkung Stage, Table 1). (●) is a High Wurmian to Late Glacial ground moraine cover on the orographic right flank of the Bote Koshi Drangka. (‘‘) are rock heads rounded by the High Wurmian ice stream network. (...) marks the level of the ice surface at that time, which has fallen away from at least 5300 m on the right to ca. 5000 m on the left. Analogue photo M. Kuhle, 03/04/2003.
Panorama from the orographic right valley flank of the lower Langmoche Drangka, i.e. the right valley flank of the main valley in the area where the Langmoche Drangka joins the middle Bote Koshi Drangka, taken at 4550 m a.s.l. (Figure 3 Panorama 186) from facing WSW with the 6180 m-peak (No. 88) in the background, facing W to the 6940 m-high Tangi Ragi Tau (No. 83), via facing WNW to the 5890 m-pass (No. 82) and the 6362 m-peak (No. 97), via facing NW to the 6263 m-peak (No. 104) up the Langmoche Drangka, up to facing NNW (right margin). (V) is ground moraine of the Holocene Nauri Stage (Table 1) in a N-exposed cirque bottom; (\(\cdot\)) large is a roche-moutoné-like and smoothed form of a Late Glacial rock ridge in the bedrock gneiss, neoglacially undercut by that N-exposed cirque glacier (V) and on the flanks already decomposed by rock crumblings (\(\cdot\)). (IV) is a Late Glacial ground moraine complex of the Sirkung Stage (Table 1), preserved as a narrow bridge between this and the cirque bottom situated behind. (C) are boulders metres in size, which are round-edged, i.e. faceted and edged. They are embedded into a clay-containing matrix. (X) is an end moraine remnant of the historical Stage X (ca. 180–30 before 1950; Table 1), ca. 200 m below the current glacier terminal. (\(\cdot\)) is a High Würmian to Late Glacial remnant of ground moraine cover, interrupted by flank abrasions in the bedrock (\(\cdot\)). (\(\cdot\)) are further glacial flank abrasions, which, in accordance with a dropping ice level, have increasingly been modified down the slope (parallel to the line of slope). (\(\cdot\)) a back-polished rock spur (Figure 3 on the right of No. 97), indicating especially clearly that the polishing, in dependence on very thick ice, must have taken place transversely to the actual direction of the cirque glacier, i.e. from the transfluence pass (\(\cdot\)) in the N, from the Chhule Drangka. From which side the 5890 m-high transfluence pass (\(\cdot\)) has been overflowed, i.e. from or to the W, is still open. The highest High Würmian abrasion lines, i.e. glacier trim-lines run about 6000–6200 m a.s.l. (\(\cdot\)). Analogous photo M. Kuhle, 05/04/2003.
Photo 188. Panorama-photo from the orographic left valley flank of the middle Bote Koshi Drangka ENE above the Marulung settlement at 4725 m a.s.l. (Figure 3). Panorama 188 from facing SSE (left margin) via facing S with the 6187 m-high Kongde Ri (No. 60), via facing SSW with the 6959 m-summit of Numbur (No. 93) and the summits of Teng Kangpoche (No. 87; 6500 m) and Panayo Tuppa (No. 86; 6696 m) in the crest in front of them, via facing SE with the 6080 m-high Gangdise (No. 92) and the summits of Teng Kangpoche (No. 87; 6500 m) and Panayo Tuppa (No. 86, 6696 m) in the crest in front of them, via facing W (right margin). In the foreground a ground moraine terrace (IV large) extends at least 500 m above the talweg. It is a remnant of the late Late Glacial ground moraine pedestal, which has filled the Bote Koshi (Figure 3). (X) are several polymictic boulders in size up to one metre, superimposed on this ground moraine pedestal; part of them is erratic. They consist of at least eight rock species: gneiss with smoky quartz, augen-gneiss, banded gneiss (second and third X from the left), fine-grained, erratic granite (X on the left in the foreground), reddish, brown, grey, quartzite, phyllite of slates and sandstones. They are edged, rounded-edged and faceted; in part secondarily frost-weathered by radial cracks. (IV white small) marks a corresponding ground moraine remnant of this pedestal- or ground moraine basement (see Figure 3 above Panorama 188). Sample 88 (see also Sample 87, No. 31) has been taken (Figure 3, 26.3.03/1) from a further remnant of this ground moraine pedestal at this level (4). (IV black, small) are further remnants of ground moraines of the late Late Glacial Sirkung Stage. Neoglacial tongue basins of hanging glaciers (V) have selectively removed these remnants. (S) are cirque-like hanging niches and hollow forms of the wall foot, in part still containing glaciers (second S from the right) (VI). The cirque bottom (S below No. 86) is covered by ground moraine of the older Dhaulagiri Stage (VI) (Table 1). High Würmian to Late Glacial remnants of a ground moraine cover, interrupted by flank abrasions in the bedrock (C, a) show back-polished rock spurs in the form of glacigenically triangular-shaped slopes. (...) is the course of the glacier trim-line of the Würmian ice stream network, reconstructed according to ground moraine covers and flank abrasions. This glacier trim-line has run from ca. 6200 m a.s.l. on the right (...) on the right below No. 83) to ca. 4400 m (...) below No. 60; Figure 3b) down into the Nangpo Tsangpo main valley. Analogue photo M. Kühle, 03/04/2003.
Photo 190. Picture taken from the orographic right valley flank of the lower Bote Kohi Drangka down-valley from the inflow of the Langmoche Drangka at ca. 4,150 m a.s.l. (Figure 3 Photo 190) from E below the highest alpine pasture of the Thame Teng hamlet facing SE down the main valley. (C) black and white on the right) are two edge boulders of augen-gneiss up to 5 m in length, between them a third round-edged boulder on which a person stands. They are situated on and in part in a moraine slope (foreground), 270 m above the valley floor (C) white on the left). (C black) are High Würmian to Late Glacial covers of ground moraine on the valley slopes, (C white) late Late Glacial ground moraine material, which, due to some process coming down from the Langmoche Drangka, has probably been reshaped during the Holocene. (C) are debris cones of dislocated ground moraine material from the upper slope. (C) (C) are High Würmian to Late Glacial flank abrasions in the bedrock, which on the steep valley slopes pierce the remnants of ground moraine. (...) are the High Würmian upper limits of abrasion and thus glacier trim-lines reconstructed at 4,700 m (... on the left) and 4,400 m (... on the right). Analogue photo M. Kuhle, 05/04/2003.
**Photo 186.** Panorama photo from the orographic right valley flank of the lower Bote Koshi Drangka at 4110 m a.s.l. (Figure 3 Panorama 191) from facing NW (left margin) diagonally upwards into the Langmoche Drangka, joining here the Bote Koshi, via facing NNW to the 5967 m peak (No. 89) along the right valley flank up the main valley, via facing NNE to Kyang Ri (No. 68, 4186 m) on the orographic left main valley flank, via facing W to the 3580 m-high Kababse (No. 52), via facing SW, looking down the Nanga-Tsongang Drangka (lower Bote Koshi valley), via facing SSE to Khandri Ri (No. 60, 6187 m), up to facing SEW into the right flank of the main valley right margin. (1) is the sampling locality of Sample Figure 82 (see also Figure 27 No. 41, Figure 3, 4.4.03/1). (1) and (2) that of Sample Figure 83 (see also Figure 37 No. 42, Figure 3, 3.4.03/1) are the orographic right lateral moraine of the neoglacial Langmoche glacier (Nauri Stage, Table 1). (IV) are remnants of ground moraines and ground moraine deposits of the late Late Glacial Shering Stage (Table 1). (C) and (C) are rounded- to one-sided rounded and edged moraine boulders of erratic granite (C on the left) and gneiss (C on the right) in size up to 60 t (3 m long stick for scale). (II) is a remnant of ground moraine of the Dhampe Stage (Table 1). (1) are High Wurmian and Late Glacial remnants of ground moraine covers. (7) are flank abrasions in the bedrock and (III) are back-polished rock spurs, showing the form of glacigenically triangular-shaped slopes; in many places ground moraines have remained on them. (7 and half-left) is the 20-year-old slides in the loose rock (moraine- or gravel material) on the valley bottom, caused by the lateral undercutting of the slope due to the outburst of the moraine lake (Dig Tsho), coming down from the Langmoche Drangka in 1985. (...) is the High Wurmian glacier trim-line running from ca. 5500 m (...) on the right somewhat below No. 89, Figure 34), via ca. 5000 m (...) on the left of No. 89 and on the right below No. 68; Figure 35), via ca. 4400 m (...) on the left somewhat below No. 73 and on the left below No. 60; Figure 36) down to 4000 m a.s.l. (...) below No. 73; Figure 31). Analogue photo M. Kuhle, 05/04/2003.

**Photo 191.** Panorama photo from the valley bottom of the middle Bote Koshi Drangka up-valley of the junction with the Langmoche Drangka taken at 4030 m a.s.l. (Figure 3 Panorama 191) across the valley chamber of the Turtazi settlement, from facing W (left margin) with the 4940 m-high summit of Tangri Ragi Tse (No. 83) in the background, via facing NW up-valley to the 5967 m-summit (No. 89) in the orographic right valley flank and via the orographic left valley flank up to facingENE (right margin). (C) is the Bote Koshi river in the talweg. (I) shows ground moraine covers and -remnants, in some places superficially reworked by debris and debris-flows cones (the two on the centre). Their material has also been dislocated in debris flow cones and -fans (V) on the very left and right (Figure 3 on the left above Panorama 191) (C) are rounded and facetted, slightly dislocated moraine boulders of far-travelled granite (e.g. second C from the left) and augen-gneiss (C large, with the inscription “Om mani padme hum” arranged in lines); the largest one is 6.5 m-long (C large). (IV–V) is the orographic left neoglacial lateral moraine of the Neoglacial Stage (Table 1) on the exit of the Langmoche Drangka, containing a late Late Glacial moraine core of the Sirkung Stage. (IV–V) are several remnants of the ground moraine pedestal from which samples have been taken. They are from the Sirkung Stage and reach altitudes up to 500 m above the talweg. (7) are glacigenic flank abrasions on the incising edges of the striae of the Lower Tibetan gneiss (6b, Nepal Geological Map 1: 125,000 (1985 Shell No. 721-B), damaged by crumblings (C) during the deglaciation in the Late Glacial. (II) are very well preserved back-polished rock spurs, which show the form of glacigenically triangular-shaped slopes and indicate the glacigenic shaping of the talus up to in excess of 5000 m a.s.l. (...) are the corresponding High Wurmian glacier trim-lines, running from ca. 5700 m (...) on the right, via ca. 5500 m (...) below No. 89; Figure 34) down to ca. 4800 m altitude (...) on the left; Figure 33). Analogue photo M. Kuhle, 26/03/2003.

**Photo 192.** Picture taken from the inflow of the Langmoche Drangka mountain river (above C and C into the lower Bote Koshi Drangka at 4110 m a.s.l. (Figure 3 Photo 92) facing NNW up the Langmoche Drangka. (V) is the inner slope of the orographic right lateral- to end moraine of the Neoglacial Stage (Table 1) of the neoglaciated Langmoche glacier. (1) are corresponding moraine material, which here, on the lower slope, has been in part re-deposited. (C) are fresh, snow-covered debris cones of dislocated moraine material from the orographic right moraine. Below (V) a crumbling edge can be observed running across the moraine slope. It has been caused by the excavation of the lower slope due to the outburst of the Dig Tsho moraine lake of the Langmoche glacier on August 8th, 1985, caused by the lateral undercutting (Photo 180). (C) is the 50-60 m-extended gravel bed developed by the water surge of the outburst of the moraine lake. (C) is an erratic boulder of tourmaline granite of 2 m in length, which several times has been redeposited glacigenically and last fluvially. Analogue photo M. Kuhle, 26/03/2003.
Photo 193. Panorama photo from the orographic right valley flank of the lower Langmoche Drangka, i.e. the right valley flank of the main valley in the confluence zone of the Langmoche into the middle Bote Koshi Drangka taken at 4550 m a.s.l. (Figure 3 Panorama 193) from facing ESE to Kang Taiga (No. 27, 6779 m) and Tramserku (No. 36, 6608 m), via facing SE to the 6187 m-high Kongde Ri (No. 60) up to facing S right margin. (black) is the High Würmian to Late Glacial ground moraine reaching up to 4600 m a.s.l. It consists of 1-3 m-long, round-edged to slightly rounded and edged polymictic boulders of metamorphites, granite (black) and gneisses (white); granite and augen-gneiss are erratic. (white) are corresponding ground moraine remnants on the left valley flank, superficially reshaped by downslope movement of debris. (white on the very left) are High Würmian (Stage II, Table 1) ground moraine remnants (cf. Figure 31) on the left valley flank in the confluence area of the Imja- and Nangpo Tsangpo Drangka (to the Dudh Koshi Nadi) reaching ca. 4300 m a.s.l. (IV and III) are orographic left moraines from the side valleys, which from the Kabzale SW-hanging-valley (IV) and the Kyajo Drangka (III) have been pushed into the main valley. (white) is a slide in this moraine material caused by the outburst of the moraine lake of the Langmoche glacier (Dig Tsho) in 1985 due to fluvial undercutting. (white) are exemplarily well-preserved, backs-polished rock spurs, which present the form of glacigenically triangular-shaped slopes and provide evidence of the glacigenic flank development up to 4400 m a.s.l. (white on the very right) are triangular-shaped slopes, showing a ground moraine cover, into which slope gullies have been eroded since the deglaciation. (white) is the High Würmian level of the ice stream network about 5000–5100 m a.s.l. (Figure 35). Analogue photo M. Kuhle, 08/11/1982.

Photo 194. Panorama photo from the orographic right valley flank of the lower Langmoche Drangka, i.e. the right valley flank of the main valley in the confluence zone of the Langmoche into the middle Bote Koshi Drangka facing NW up the Bote Koshi Drangka via the Orsha hamlet (buildings on the left, middle ground) to the 3880 m peak (No. 89). (V) is the outer slope of the orographic right lateral-to-end moraine of the Langmoche glacier (Nauri Stage, Table 1) at the exit of the Langmoche Drangka. This neoglacial lateral moraine has a Late Glacial ground moraine core. (IV) is the late Late Glacial terrace of the ground moraine pedestal of the Sirkung Stage (Table 1) in the triangular-shaped inset between the Bote Koshi- and Langmoche Drangka. 400 m above the main valley bottom, (white) are High Würmian to Late Glacial remnants of ground moraine covers and – pedestals, in places exposed by fresh slides. (white below No. 73) are High Würmian to Late Glacial remnants of ground moraine covers and – pedestals, in places exposed by fresh slides. (white) is a neoglacial, glaciofluvial gravel cover. (white) marks a classic, glacigenically triangular-shaped slope. (white) are postglacial rock rolls, developed since the deglaciation. (white) is the High Würmian level of the ice stream network about 5000–5100 m a.s.l. (Figure 35). Analogue photo M. Kuhle, 08/11/1982.
Photo 195. Panorama photo from up-valley of the junction of the Arabtsen Drangka and the lower Bote Koshi, i.e. Nangpo Tsangpo Drangka (taken at 3800 m a.s.l. (Figure 3). Panorama 195) from facing SW (left margin) and WSW up the Arabtsen Drangka to the 6300 m-high Teng Kangpoch (No. 87), via facing NNW up the Bote Koshi Drangka via the Orsha hamlet (buildings on the left, middleground) to the 5967 m-peak (No. 89), up to facing NE to the 5583 m-high Kabsale (No. 92). In addition, the meltwaters of still younger margins of the hanging glaciers have modified the ground moraine terrace. (V) is the outer slope of the end moraine of the Holocene Arabtsen glacier, shaped in the Nauri Stage (Table 1). (S) is several gneiss boulders in size from metres up to that of a house, black on the moraine slope ( large black, white) are exposures of slides on the sediments of the valley bottom, developed, i.e. enlarged by fluvial undercutting due to the outburst of the moraine lake of the Langmoche glacier (Dig Tsho) on August 4th, 1985 (cf. Photo 194 from 1982) (large black). (S) are glacigenic flank abrasions, the upper limits of which, in combination with the glacigenically triangular-shaped slopes as a result of back-polished mountain spurs, provide evidence of the High Würmian glacier trim-line (...). The glacier trim-line has run between 5200–5000 m a.s.l. (... on the right below No. 87 and on the left of No. 89; Figure 35) and 4800–4700 m a.s.l. (on the left of No. 92). The Kabsale SW-hanging valley is an early- to Late Glacial tube cirque with a trough-shaped cross-profile (S); (I) shows a postglacial rock crumbling and a slope of boulder debris. Analogue photo M. Kuhle.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 196. Panorama photo at 4200 m from the valley floor (Figure 3 Panorama 196) into the valley head of the Arabtsen Drangka from facing SW (left margin) via WSW into the N-face of Panayo Tupsa (No. 86, 6996 m) and to the 6718 m-high Pophurago Shar (No. 85) with the Thengpo alpine pasture in the middleground (below ● white), via facing WNW to the 6180 m-peak (No. 88), up to facing NW (right margin). (●) is the sampling locality of the C14-dating (Figure 3 and Table 2: No. 10). (X white) is the orographic right lateral moraine of the Thengpo glacier during the historical Stage X (Table 1); on the right of (X white) the contemporaneous Thengpo glacier is situated, covered with surface moraine. (VII) on the orographic right side is a triple ledge of lateral moraine of its Younger Dhaulagiri Stage. (X–XII) shows the front moraine of the corresponding stages (Table 1) of the 6180 m-peak ESE-glacier, flowing down from a cirque (● large). (V) is a neoglacial moraine remnant of the Nauri Stage belonging to the Thengpo glacier, which as time was wise: as wide. (● white) is a terrace-shaped lateral remnant of a ground moraine pedestal. (IV) are two late Late Glacial remnants of a ground moraine pedestal of the Nauri Stage, interrupted since the deglaciation by the inflow of the orographic left tributary valley and separated from each other by erosion. (● small) are polymictic moraine boulders in size from metres up to that of a hut, transported out of the moraine formation and re-sedimentated. (● black) are remnants of ground moraine cover on the orographic right valley flank. (● black) is a debris or debris flow covered with material from wall crumblings and dislocated ground moraine; (● white) is a steep debris cone with a core made up of ground moraine and a surface of debris of crumblings. (●) are more or less well-preserved glacigenic roundings of abrasion on the Lower Tibetan gneiss bedrock (6b); on the flat, nearly horizontal rock bottoms these forms show the character of roches moutonnées (the two ▲ on the right). The glacier trim-line (—), reconstructed according to the upper limits of abrasion, has reached an altitude of ca. 6200 m a.s.l. at the valley head (below No. 85). To the E (— on the left margin and on the left below No. 86) it runs down to ca. 5800 m. Analogue photo M. Kuhle, 09/11/1982.

The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 196. Photo 197. Panorama photo from the exit of the highest orographic left side valley at the valley head of the Arabtsen Dzhangka at 4780 m a.s.l. (Figure 3, Panorama 197) into the head of this side valley, from facing WNW (left margin) via facing NNW (centre of the panorama) up to facing ENE (right margin). (X, X–XI and X–XII) are historic end moraines and youngest glacier positions (Table 1) of the short hanging glaciers visible from this viewpoint, which flow down from the Tsuchi Labra (pass) (No. 84) to the SE (X, X–XI) and from the 6180 m peak to the S (No. 88) (X–XII) (cf. Figure 3 below No. 88). (IV) is a late Late Glacial moraine remnant of the Sirkung Stage (Table 1); (V) are neoglacial moraine bodies of the Nauri Stage. (ob.) mark High Würmian to Holocene remnants of ground moraine, which chronologically are not to be classified in more detail. (ob. below) shows yak kraals enclosed by stone walls. (ob.;) show fresh rock crumblings; (ob.;) are debris cones fed by fresh crumblings. (ob.) show glacigenically polished-back mountain spurs, for the last time abraded during the Würmian ice stream network. (… from left to right) are the Würmian glacier trim-lines at ca. 6200 m, 5900 and 5700 m a.s.l. Analogue photo M. Kuhle, 09/11/1982.

The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 364. Panorama photo from the orographic left slope of the lower Arabtsen Drangka at 4340 m a.s.l. (Figure 3, Panorama 190) from facing NNW (left margin) along the orographic left flank of the Arabtsen Drangka and into the left flank of the Bose Khoshi Drangka in the background, via facing NNE to Kabola (No. 92, 5903 m), via facing ENE to the 5371 m high Khumbi Yal Li (No. 74) and the summit of the 6856 m high Ambu Deleung (No. 20), via facing W down the Nangpo Tsangpo Drangka and to the 6779 m high Kuk Ha Tenga, up to facing NE into the orographic left flank of the Nangpo Tsangpo Drangka (right margin) (C) is the current glaciofluvial gravel floor of the Arabtsen Drangka river. (o) on the left below No. 52 is the end moraine of a contemporaneous cirque glacier; the rest of the (o) are covers of ground moraine on the valley bottom and the flanks of the Arabtsen Drangka below on the very left, on the very right and in the middle below (somewhat right below No. 20) are covers of ground moraine on the orographic left slope of the Nangpo Tsangpo Drangka main valley reaching up to a height of 4100 m a.s.l. (V white; cf. Figure 36). (V) are the neoglacial end moraines of the Nauri-Stage (Table 1), forming the tongue basin with the Thame settlement. (V black) shows the sampling locality of Figure 36. (V) is a High Würmian to Late Glacial cirque in the catchment area of the Kuk Ha SW-hanging valley. (C) are debris cones, which further below pass into debris flow cones and fans. At some places of the catchment area very coarse to coarse-blocky debris of crumblings is visible (5 black). (w) are further crumblings, oriented according to ice-marginal and subglacial hollow forms of drainage (5 white) is a subglacially developed Late Glacial drainage tube, i.e. ravine, which due to crumblings has been extended since the deglaciation. (w), (w) are glacigenic abrasions on the faces of gneiss bedrock preserved between the crumblings. (...) is the High Würmian (Stage 0, Table 1) upper limits of abrasion. It runs from (... on the left) at ca. 5000 m (Figure 35 left side), via 4400 m (... on the right below No. 74; Figure 36 on the left) down to 4000 m a.s.l. (... on the left below No. 27; Figure 52 left side). Analogue photo M. Kuhle, 08/11/1982.
Photo 200. Picture taken at 3640 m a.s.l. from the orographic left flank of the lower Bote Koshi i.e. Nangpo Tsangpo Drangka from down-valley of the confluence with the Arabtsen Drangka (below No. 85) W of the Samde settlement (Figure 3, Photo 200) facing W up the Bote Koshi (on the right) and the trough-shaped Arabtsen Drangka (on the left) on to the 6500 m-high Teng Kangpoche (No. 87) and the 6718 m-high Pigpherago Shar (No. 85). (C) is the Bote Koshi river, which cuts into the ground moraine pedestal of the late Late Glacial Sirkung Stage (IV); (D) moraine material in situ, which recently and to an increasing extent has been fluvially undercut by the outburst of the moraine lake of the Langmoche glacier (Dig Tsho) in 1985. (E) are cones and slopes of the moraine material tipped over since that time; (F) are facetted moraine boulders, exposed by the stream in the talweg; (G) are eroded moraine boulders up to the size of a hut consisting of gneiss and granite. (V) shows an orographic left end moraine of the Arabtsen glacier, which during the Nauri Stage (Table 1) has been thrust across the ground moraine pedestal of Stage IV. (I) are ground moraine cones, in part superficially reshaped by debris cones (the two black below No. 87). The highest occurrences have been observed at 4900 m a.s.l. (G) is a glacigenically back-polished mountain spur and triangular-shaped slope; (H) are glacigenic forms of abrasion in the rock. The upper limit of all these forms, i.e. their polish line (...), provide evidence of the High Würmian (Stage 0) valley glacier level. It has run at about 5800 m (... on the right below No. 87) and has fallen away to the inflow of the Arabtsen Drangka at ca. 4500 m (on the left below No. 87). Above the orographic right main valley flank the ice level has run at about 5000 m a.s.l. (the two ... on the right). Analogous photo M. Kuhle, 07.04.2003.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Pano panorama photo taken from the orographic left slope of the lower Arabtsen Drangka at 3910 m a.s.l., 110 m above the Arabtsen Drangka talweg (\(\text{\textbullet}\) on the right) (Figure 3, Panorama 199), from facing NNW (left margin) along the orographic right flank of the Bote Koshi Drangka on to the 5967 m-peak (No. 89), via facing NE to Kabdale (No. 92, 5830 m), via facing SSW to the 5583 m-high Kang Taiga (No. 27), via facing SSW to the 5583 m-high Kang Taiga (No. 73), down the Nangpo Tsangpo, i.e. lowest Bote Koshi Drangka, via facing S to the 6500 m-high Teng Kangpoche (No. 87), up the Arabtsen Drangka, up to facing W into its left flank (right margin). The sampling locality of Figure 85 (see also Figure 37, No. 46) is the late Late Glacial (Stage IV) material of a ground moraine pedestal (\(\text{\textbullet}\) on the right) with a peripheral modification by a neoglacial orographic left lateral moraine of the Arabtsen tributary glacier (V black in the foreground of the Nauri Stage (see Table 1). (\(\text{\textbullet}\) white) is the corresponding right lateral- to end moraine. (\(\text{\textbullet}\) black) are edged to round-edged gneiss- and granite boulders up to 3 m in length (person for scale). (V black, small) is a neoglacial end moraine in the confluence area of the Langmo che Drangka. (IV large) is furrowed ground moraine of the Sikung Stage on the valley slope; (IV small) is the correspondingly old ground moraine core of a ground moraine pedestal, reshaped by the meltwater of the neoglacial Kabdale SW-cirque glacier. (\(\text{\textbullet}\) large, half-left and half-right below No. 92) and mantlings of the slope by ground moraine, (\(\text{\textbullet}\) black) are cone forms modifying the ground moraine covers; they have a morainic core. (\(\text{\textbullet}\) white) is an active debris flow fan. (\(\text{\textbullet}\) black) is an actively degrading glacier. (\(\text{\textbullet}\) white) marks a current fluvial cut by backward erosion of the Arabtsen river into the ground moraine plate on which the Thame settlement is situated. (\(\text{\textbullet}\) black) are glacigenically back-polished mountain spurs and triangular-shaped slopes in the rock, for the last time abraded during the Würmian ice stream network; (\(\text{\textbullet}\) white) are clearly preserved glacigenic roundings of abrasion on the faces of gneiss rock. (\(\text{\textbullet}\) small, half-left and half-right below No. 92) are glacigenically back-polished mountain spurs and triangular-shaped slopes in the rock. (\(\text{\textbullet}\) white) is the High Würmian (Stage 0, Table 1) glacier trim-line reconstructed according to the ground moraine covers and upper limits of abrasion. It runs from (\(\text{\textbullet}\) on the very left) from ca. 5300–5000 m (Figure 35 on the left), via 4600–4400 m (on the right below No. 92) down to 4200–4000 m a.s.l.; (\(\text{\textbullet}\) on the right below No. 36; Figure 52 on the left side) and from ca. 5000 m a.s.l.; (\(\text{\textbullet}\) on the right down to ca. 4700–4500 m (on the left below No. 40). (\(\text{\textbullet}\) white) is an Ice Age to neoglacial cirque. (\(\text{\textbullet}\) white) marks a sharp wall cut without a catchment area, developed as a subglacial meltwater rivine. Analogue photo M. Kuhle, 06/04/2003.

\[\text{\textbullet}\] Photo 199. Panorama photo taken from the orographic left slope of the lower Arabtsen Drangka at 3910 m a.s.l., 110 m above the Arabtsen Drangka talweg (\(\text{\textbullet}\) on the right) (Figure 3, Panorama 199), from facing NNW (left margin) along the orographic right flank of the Bote Koshi Drangka on to the 5967 m-peak (No. 89), up the main valley into the left flank of the Bote Koshi Drangka in the N, via facing NE to Kabdale (No. 92, 5830 m), via facing SSW to the 5583 m-high Kang Taiga (No. 27), via facing SSW to the 5583 m-high Kang Taiga (No. 73), via facing S to the 6500 m-high Teng Kangpoche (No. 87), up the Arabtsen Drangka, up to facing W into its left flank (right margin). (\(\text{\textbullet}\) white) is the corresponding right lateral- to end moraine. (\(\text{\textbullet}\) white) is an active debris flow fan. (\(\text{\textbullet}\) black) is an actively degrading glacier. (\(\text{\textbullet}\) white) marks a current fluvial cut by backward erosion of the Arabtsen river into the ground moraine plate on which the Thame settlement is situated. (\(\text{\textbullet}\) black) are glacigenically back-polished mountain spurs and triangular-shaped slopes in the rock, for the last time abraded during the Würmian ice stream network; (\(\text{\textbullet}\) white) are clearly preserved glacigenic roundings of abrasion on the faces of gneiss rock. (\(\text{\textbullet}\) small, half-left and half-right below No. 92) are glacigenically back-polished mountain spurs and triangular-shaped slopes in the rock. (\(\text{\textbullet}\) white) is the High Würmian (Stage 0, Table 1) glacier trim-line reconstructed according to the ground moraine covers and upper limits of abrasion. It runs from (\(\text{\textbullet}\) on the very left) from ca. 5300–5000 m (Figure 35 on the left), via 4600–4400 m (on the right below No. 92) down to 4200–4000 m a.s.l.; (\(\text{\textbullet}\) on the right below No. 36; Figure 52 on the left side) and from ca. 5000 m a.s.l.; (\(\text{\textbullet}\) on the right down to ca. 4700–4500 m (on the left below No. 40). (\(\text{\textbullet}\) white) is an Ice Age to neoglacial cirque. (\(\text{\textbullet}\) white) marks a sharp wall cut without a catchment area, developed as a subglacial meltwater rivine. Analogue photo M. Kuhle, 06/04/2003.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya
Photo 201. Picture taken at 3590 m a.s.l. (Figure 3, Photo 201) from the ravine-like talweg of the lower Bote Koshi Drangka, set in decametres-deep, in the confluence area of the Arabtsen Drangka E of the Thame Og settlement looking up-valley facing NW. (⊙) is an avalanche cone, which has reached the Bote Koshi river and shortly dammed up. (□ black) are potholes and pothole-walls, still annually reached and reworked by the high water. (◇ white) are bow-shaped remnants or parts of potholes in dimensions of 1.4 m, 6.8 m above the stream. (●) marks a 3.3×1.9 m extended niche of crumblings in the outcropping massive. (n black) are pothole-walls, still annually reached and reworked by the high water. (n white) are bowl-shaped remnants or parts of potholes in dimensions of 1–4 m, 6–8 m above the stream. (n white) marks a 3.3×1.9 m extended niche of crumblings in the outcropping massive. Analogue photo M. Kuhle, 25/03/2003.

Photo 203. Picture taken at 3650 m from the ground moraine pedestal (large) at the exit of the Arabtsen Drangka, E of the Thame Og settlement, facing ESE on to the 6779 m-high Kang Taiga (No. 27), the 6608 m-high Tramserku (No. 36) and the 6369 m-high Kusum Kanguru (No. 73), down the Nangpo Tsangpo, i.e. lower Bote Koshi Drangka. (◇) is the main valley river, the bed of which has recently been widened due to the increasing fluvial lateral erosion, caused by the flood wave of the outburst of the moraine lake of the Langmoche glacier (Dig Tsho) in 1985. (△) are slight breaks of landslips, cones and slopes, made up of the ground moraine material, which at the same time has been tipped over. In November 1982 the author has still walked the two trails (●, on the right), which are broken off now. (\\̣, \̣) are glacial abrasion forms of the orographic left flank, in part mantled by remnants of ground moraine covers (n small) (Figure 36). (III) is the Dhampu Stage (Table 1) end moraine of the orographic left tributary valley glacier, the Kyajo glacier. (... on the right below No. 27) shows the High Würmian glacier level about 4240 m a.s.l. on the mountain ridge between the Kyajo Drangka and the Khumde settlement beyond. (... on the right below No. 36) is the course of the glacier trim-line in the confluence area of Imja- and Nangpo Tsangpo about 4300–4200 m (Figure 32) and (... below No. 73) at ca. 4100–4000 m in the area where the Kyashar Khola joins the Dudh Koshi Nadi (Figure 52). Analogue photo M. Kuhle, 06/04/2003.

Photo 202. Picture taken at 3640 m a.s.l. (Figure 3, Photo 202) from the ground moraine pedestal (large) at the exit of the Arabtsen Drangka, E of the Thame Og settlement, facing NNE into the orographic left flank of the lower Bote Koshi Drangka. (C) is one of many well-rounded erratic granite boulders (person for scale) of the ground moraine pedestal (large), lying on a glacigenically polished and rounded rock bottom (small) of the outcoursing valley underground. On the abraded gneiss wall (large) remnants of subglacial potholes, in size 2–6 m, are situated (●). They are very freshly preserved as half-hollows up to at least 50 m above the current river (Photo 101 n black). (C) is a collapse of a rock face (Photo 101 n black), through which snow avalanches nowadays come down, reaching the Bote Koshi river (Photo 101 △). Analogue photo M. Kuhle, 25/03/2003.
Photo 206. Picture taken from the orographic left flank of the Nangpo Tsangpo Drangka between the Dramo (on the right of the right white n) and Gonglha settlements at 3350 m a.s.l. (Figure 3, Photo 206), ca. 120 m above the talweg (h black) facing WNW up the Nangpo Tsangpo valley via the valley chamber of Dramo on to the 6180 m-peak (No. 88). (h white) is an alluvial fan derived from a channel on the orographic right side of the slope, adjusted to the gravel floor of the valley (h black). (h white) is a debris flow cone of dislocated ground moraine from the orographic right trough valley slope. (m black) is the course of a glacial ravine with an overlay of ground moraine. (IV) marks the remnant of a late Late Glacial ground moraine pedestal (Sirkung Stage; Table 1); (V) is a neoglacial end moraine complex (Nauri Stage), thrust across by the Arabtsen glacier. (n white) are covers of ground moraine with a thickness of decametres. Owing to this, they cannot be confused with covers of weathering- and slope debris. (s white) is one of the boulders in size of metres up to that of a hut (person for scale) from which the moraine covers are built up. (w white) is a classic, glacigenically triangular-shaped slope (Figure 3 on the left above Panorama 198). (˙, ˙) are rock ribs, piercing through the ground moraine covers. They show glacigenic abrasions, which have rounded the gneiss bedrock. (...) is the Wu¨rmian (Stage 0, Table 1) surface height of the valley glacier verified according to the upper limits of abrasion: (...) on the left and right has run at 4400–4300 m a.s.l. (Figure 36, c, below No. 88) is the glacier trim-line at ca. 5300 m a.s.l. (c black) is an Early- to Late Glacial cirque depression, flatly set into the orographic left valley flank. Analogue photo M. Kuhle, 25/03/2003.

Photo 204. Picture taken at 3670 m a.s.l. (Figure 3, Photo 204) from the orographic left flank of the Nangpo Tsangpo, i.e. lower Bote Koshi Drangka N above the Thomde settlement (c white) ca. 200 m above the talweg (c black). Facing SE down the Nangpo Tsangpo, i.e. lower Bote Koshi Drangka, (m) are ground moraine covers recognizable in this valley section up to at most 4200–4300 m a.s.l. (h white) are the very top and second from the right (Figure 32). (m large) are the mantlings with ground moraine on the trough flanks in Profile 26 (Figure 36), see Figure 3. (7) is the sampling locality of Figure 86 (see also Figure 37, No. 45). (c) are edged to round-edged and faceted granite boulders, 'swimming' in the fine material matrix. (c white) shows a remnant of the ground moraine pedestal on which the Thomde settlement is situated, glaciofluvially flattened since the Late Glacial deglaciation. It corresponds with the level of ground moraine (h white) on the very right on the right valley side. (h black) is a current debris flow fan, which has been – and still is – buildup of dislocated moraine from the orographic right valley slope. (III) is the orographic right lateral- to end moraine of the Dhampa Stage (Table 1) of the orographic left tributary valley glacier, the Kyajo glacier, which at that time had reached the main valley. (7) is an outer slope of the Bote Koshi (river in the older ground moraine material), i.e. in the underlying bed of this end moraine. It has been increasingly undercut by the flood wave due to the outburst of the moraine lake of the Lungmoche glacier (Dig Tsho) in 1985, so that fresh slides and crumblings have taken place as far as into the deposits of end moraine in the hanging layer. (s white) is a glacigenically back-polished mountain spur and triangular-shaped slope (Figure 3) on the right below Photo 84. (7, ˙) are glacigenic abrasion forms in the rock. Due to their upper limits, i.e. the polish lines developed (...), all these forms provide evidence of the High Wu¨rmian (Stage 0) valley glacier trim-line; it runs (...) on the left and right in the middle of the bedrock. (˙, ˙) are covered of moraine with a thickness of decametres. Owing to this, they cannot be confused with covers of weathering- and slope debris. (c white) is one of the boulders in size of metres up to that of a hut (person for scale) from which the moraine covers are built up in a classic, glacigenically triangular-shaped slope (Figure 3 on the left above Panorama 198). (7, ˙) are rock ribs, piercing through the ground moraine covers. They show glacigenic abrasions, which have rounded the gneiss bedrock. (c black) is an Early- to Late Glacial cirque depression, flatly set into the orographic left valley flank. Analogue photo M. Kuhle, 25/03/2003.
Panorama photo at 3300 m a.s.l. from the orographic left slope of the lower Bote Koshi, i.e. Nangpo Tsangpo Drangka S of the Mende settlement (Figure 3, Panorama 205), facing SW into the right valley flank (left margin), via facing WNW up the trough valley (i), up to facing NNW into the orographic left valley flank (right margin). (v) is a rock threshold in the Lower Tibetan gneiss (6b), i.e. here a trough threshold, dividing the valley by a trough basin, which has been subglacially-glaciofluvially dissected. The wall of the ravine-like incision shows current crumblings (vi; the light rock faces). (iv) is the remnant of a decametre-thick late Late Glacial ground moraine pedestal (Sirkung Stage; see Table 1); (iv) is a neoglacial end moraine complex, thrust across the ground moraine pedestal by the Arabtsen glacier. (iii) are flat, Early- and Late Glacial cirque forms (karoids). (v) is current debris below the back wall of a cirque. (iv) are small-scale ground moraine covers on the trough valley flanks (Figure 36), reaching 4600 m a.s.l. (vi) is a classic, triangular-shaped slope (Figure 3 on the left above Panorama 198), the form of which is due to a truncated spur. (. . .) is the High Würmian glacier level at ca. 4300 m a.s.l. reconstructed according to an abrasion limit (Figure 36, Profile 26 on the right side). Analogue photo M. Kuhle, 01/09/1982.
Photo 208. Picture from the orographic left side of the exit of the Kyajo Drangka taken at 3440 m a.s.l. (Figure 3, Photo 208) facing NNE up the trough-shaped Kyajo Drangka on to the 5761 m-high massif of Khumbui Yul Lha (No. 74). The valley has a steep step (below) (Photo 209), which in the cross-profile is flatly and broadly developed. (\(\bullet\)) are the youngest accumulations on the valley bottom from glaciofluvially reshaped ground moraine with a cover of gravel and debris flow fans. (\(\bullet\)) marks a debris cone, which has been – and still is – built up of rock crumblings and dislocated ground moraine (\(\bullet\)). (\(\bullet\)) are rock ribs, piercing through the ground moraine covers. They show glacigenic abrasions, which have rounded the bedrock gneiss. (\(\bullet\)) are truncated spurs, back-polished by the glacier ice. (...) is the corresponding High Würmian glacier trim-line at ca. 4300–4400 m a.s.l. Analogue photo M. Kuhle, 25/03/2003.

Photo 207. Panorama photo from the orographic right side at the exit of the Kyajo Drangka S of the Mende settlement taken at 3500 m a.s.l. (Figure 3, Panorama 207) facing ENE (centre of the panorama) on to a mountain spur, which belongs to the orographic left flank of the exit of the Kyajo Drangka as well as to the orographic left slope of the Nangpo Tsangpo Drangka (main valley). (\(\bullet\)) is the sampling locality of Figure 63 (see also Figure 37, No. 30) on the mountain ridge behind which the Khumde settlement is situated. (\(\bullet\)) are small-scale abrasion roundings in relatively thin-stratified gneiss (6b); (\(\bullet\)) are decametre-thick covers of ground moraine up to an altitude of 3000 m a.s.l.; (\(\bullet\)) on the right shows the place where a very thick accumulation of ground moraine has developed an iron-shaped, even remnant, covered by several boulders in size of a hut up to that of a house (\(\bullet\)). (\(\bullet\)) marks a saddle between the outcropping mountain slope and an accumulation of ground moraine. (\(\bullet\)) is the High Würmian glacier trim-line at least 2240 m a.s.l. Analogue photo M. Kuhle, 01/09/1982.

The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 209. Picture taken from the orographic left side of the exit of the Kyajo Drangka at 3440 m a.s.l. (Figure 3, Photo 209) facing N up the trough-shaped Kyajo Drangka onto a steep step in its longitudinal course on which moraine material is situated (II), deposited by the Kyajo glacier of the late Late Glacial Sirkung Stage (IV). The classically glacigenic polish forms of the bottom of the flatter-ribbed rock of the step-step in the gneiss rock (III) below IV and on the right below IV, exhibits a characteristic steep fall on the lee-side, i.e. a break-off (IV), which might have been subglacially developed by erosion. The old age of this break-off can be recognized by its dark colour due to water stains. (I) on the right are clear traces of abrasion by flank polishing on the rock faces of the trough flanks. (C) are Holocene to historical-situated niches of crumbling, still sharp-edged and flat, which have been developed according to the banking structure of the gneiss. Analogue photo M. Kuhle, 01.09.1982.

Photo 210. Panorama photo from the orographic left side in the Nangpo Tsangpo Drangka and at the same time also from the orographic left at the exit of the Kyajo Drangka from NW of the Gonglha settlement taken at 3340 m a.s.l. (Figure 3, Panorama 210) from facing WSW (left margin) with the orographic right flank of the Nangpo Tsangpo, via facing WNW up the trough-shaped main valley (Figure 36) on to the 6480 m peak (No. 88), via facing NW into the orographic left flank of the Nangpo Tsangpo Drangka flank and the junction with the Kyajo Drangka (left), via facing NW on to the 6480 m peak (No. 88), via facing NNW (right slope) on to a ground moraine slope. (II) is the end moraine of the Kyajo glacier, deposited during the Dhampu Stage (Table 1). On its inner slope several field terraces and new houses can be observed. (II) marks a remnant of lateral or ground moraine, the level of which has been reached and reworked by the joint Bote Koshi (Nangpo Tsangpo-) and Kyajo glaciers for the last time during the Late Glacial Taglung Stage. (IV) is the remnant of ground moraine at the exit of the Arabtsen Drangka across which the neoglacial end moraine of the Arabtsen glacier (V) has been thrust. (I) are ground moraine covers, reaching here up to 4900 m (on the right below No. 88) and in many places covering the glacigenic flank abrasions (I), (C) are mountain spurs back-polished by the High Würmian to early Late Glacial glacier ice and developed to glacigenically triangular-shaped slopes. The highest flank abrasion reaches up to 4900 m a.s.l. (III) on the very left and (IV) (cf. Figure 36) on the left and (IV) (cf. Figure 36). (C) below No. 88) mark the High Würmian glacier surface about 5300 m and ca. 4900 m a.s.l. (the rest of...). (C) are flatly inset, bowl-shaped erosional forms of small Late Glacial hanging glaciers, which could be genetically classified as cirques. (I) is the orographic right wall of a subglacially developed moraine, set off with a crumbling edge against the much flatter, orographic right trough valley flank (analogue Photo 211). Analogue photo M. Kuhle, 25.03.2003.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya

Photo 212. Picture taken at 3050 m a.s.l. from the spur between the left flank of the Nangpo Tsangpo (lower Bote Koshi) Drangka down-valley of the junction with the Kyajo Drangka, half-way between the Gonggla and Namche Bazar settlements, from facing ESE (left margin) along the orographic left flank, down the Nangpo Tsangpo Drangka with the 6069 m-high Tsermar Wa (No. 36), via facing SE to the 3939 m-high Kasum Kangarwa (No. 70), via facing SW (right margin) into the orographic right main valley flank. (□) are ground moraine covers, here reaching a height up to 4300 m (on the left below No. 73) and covering the glacigenic flank abrasions at many places (○, □). (○) on the right below) is an early Late Glacial (Stages I and II) remnant of a ground moraine pediment. (□ white) are gneiss- and granite boulders in situ, which have also built-up the ground moraine cover on the orographic left slope. (△) are glacigenically triangular-shaped slopes developed by flank abrasion. (○, □) are uppermost limits of glacier polishing the High Würmian glacier trim-line at ca. 4300 m a.s.l. (Figure 32, Profile 22 on the left side). (□ on the right below No. 73) is the orographic left polisher line in the main valley of higher order continuing down-valley, the Dudi Koshi Nadi, at ca. 4000 m a.s.l. (Figure 52, Profile 28 on the left side). (□ black) is a NE-exposed early-, High-, Late- to neoglacial cirque from WNW of the Kongde alpine pasture in the Kongde Rimausif. (○) mark the subglacially developed ravine-like meltwater gorge cut into the very wide main valley bottom, which in many places is trough-shaped (Figure 36). Analogue photo M. Kuhle, 25/03/2003.

Photo 211. Panorama photo taken at ca. 3500 m a.s.l. (Figure 3, Panorama 211) from the orographic left flank of the Nangpo Tsangpo (lower Bote Koshi) Drangka down-valley of the junction with the Kyajo Drangka, half-way between the Gonggla and Namche Bazar settlements, from facing ESE (left margin) along the orographic left flank, down the Nangpo Tsangpo Drangka with the 6069 m-high Tsermar Wa (No. 36), via facing SE to the 3939 m-high Kasum Kangarwa (No. 70), via facing SW (right margin) into the orographic right main valley flank. (□) are ground moraine covers, here reaching a height up to 4300 m (on the left below No. 73) and covering the glacigenic flank abrasions at many places (○, □). (○) on the right below) is an early Late Glacial (Stages I and II) remnant of a ground moraine pediment. (□ white) are gneiss- and granite boulders in situ, which have also built-up the ground moraine cover on the orographic left slope. (△) are glacigenically triangular-shaped slopes developed by flank abrasion. (○, □) are uppermost limits of glacier polishing the High Würmian glacier trim-line at ca. 4300 m a.s.l. (Figure 32, Profile 22 on the left side). (□ on the right below No. 73) is the orographic left polisher line in the main valley of higher order continuing down-valley, the Dudi Koshi Nadi, at ca. 4000 m a.s.l. (Figure 52, Profile 28 on the left side). (□ black) is a NE-exposed early-, High-, Late- to neoglacial cirque from WNW of the Kongde alpine pasture in the Kongde Rimausif. (○) mark the subglacially developed ravine-like meltwater gorge cut into the very wide main valley bottom, which in many places is trough-shaped (Figure 36). Analogue photo M. Kuhle, 25/03/2003.
Photograph 213. Taken at 2950 m a.s.l. in the confluence area of the Nangpo Tsangpo and Imja Drangka at the source of the Dudh Kosi Nadi, in the left flank of the main valley of the highest order (Figure 3 and 4 Photo 213) facing NNW on to two forms of potholes (\(\vec{\cdot}\)). They are several metres in diameter (persons for scale; the sticks are 1.6 m long) and are situated on a rock ledge in the vertical wall of the subglacial gorge, ca. 50 m above the current gravel floor of the Dudh Koshi river. Analogue photo M. Kuhle, 7/4/2003.

Photograph 214. Taken at ca. 3000 m a.s.l., 120 m above the talweg, from the orographic left flank of the Dudh Koshi Nadi halfway between the Jorsale and Monjo settlements (27\(^\circ\)47'15" N/86\(^\circ\)44'25" E; Figure 4, Photo 214), facing NNW looking up-valley. 1. white) is an angular grey mica gneiss boulder (6b) in size of a hut, moulded as a mani-stone, which as a crumbled boulder belongs to the local moraine. 2. black) marks a terrace of round-edged to rounded polymict boulders in size of metres, derived from glaciofluvially coalesced ground moraine. 3. white) are glacigenic flank abrasions, testifying to a slightly trough-shaped-concave, i.e. glacigenically polished out valley cross-profile. This trough form \(\vec{\cdot}\) reaches down to the bends of the profile \(\vec{\cdot}\) (black). below, the box-shaped, steep cross-profile of the subglacial meltwater gorge sets in. 4. black) are postglacial rock crumblings, which, due to their lighter colour can in some places be diagnosed as being historical to recent. \(\vec{\cdot}\) is the High Würmian glacier trim-line (Stage 0, Table 1) about 4000 m a.s.l. 6. black) are the Late Glacial terraces of a ground moraine pedestal in the confluence inset of the Namche settlement about 3500 m a.s.l. (Figure 3, I on the left of Photo 84). Analogue photo M. Kuhle, 10/3/2003.

Photograph 215. Taken at ca. 2850 m a.s.l., 80 m above the talweg and the gravel floor (\(\vec{\cdot}\)) from the orographic left flank of the Dudh Koshi Nadi near the Monjo settlement (27\(^\circ\)47'15" N/86\(^\circ\)44'25" E; Figure 4 Photo 215), facing WNW looking into the orographic right valley flank. (\(\vec{\cdot}\)) is a gneiss (metamorphic) boulder in size of a house; (\(\vec{\cdot}\)) are far-travelled granite boulders. \(\vec{\cdot}\) is material of a debris flow cone or -fan, undercut by the Dudh Koshi river, i.e. by the surge of the outburst of the moraine lake of the Langmoche glacier. \(\vec{\cdot}\) are subglacial meltwater channels laid out as a bottom line in the valley flank from which the debris flow material (\(\vec{\cdot}\)) of displaced ground moraine was transported. \(\vec{\cdot}\) are glacigenic flank abrasions with forms of rounded knobs, and band polishings of outcropping edges of the stratum in the grey mica gneiss bedrock. The upper limit of which provides evidence of a High Würmian ice level \(\vec{\cdot}\) at 4000–4000 m a.s.l. (Figure 51). \(\vec{\cdot}\) are postglacial rock crumblings roughening the flank abrasions. Analogue photo M. Kuhle, 10/3/2003.
Photo 218. Picture at ca. 2810 m a.s.l., ca. 140 m above the talweg and the gravel floor (C), taken from the orographic right flank of the Dudh Koshi Nadi S of the Bengkar settlement (above 27°45′45″ N 86°47′18″ E; Figure 4, Photo 216), facing NE up-valley looking on to Trumkerka (No. 36, 6008 m; (h) is a ground moraine remnant the surface of which has been glaciofluvially smoothed, and (n) on the right above) a glaciofluvial terrace with a great density of large boulders which from this ground moraine level have been glaciofluvially condensed by the removal of the matrix. (C) is the current gravel floor of the Dudh Koshi river, which, due to the flushing out of matrix, presents a further condensation of the morainic portion of coarse boulders at a 10 m lower level. (h) on the left and right) are two cones of moraine debris, i.e. debris flow, built up of ground moraine, which has been dislocated downslope. (h, n) mark glaciofluvic flank abrasions in the Lower Tibetan grey mica gneiss (6b; Nepal Geological Map 1:125,000, 1985: Sheet No. 71B) reaching up to 4000 m a.s.l. (h, on the left; Figure 32) and 4000 m (h, on the right; Figure 52), thus indicating the High Würmian glacier trim-line. (n) are postglacial rock crumbling, which are the characteristic reshaping of glaciofluvially oversteepened trough valley flanks worldwide. Analogue photo M. Kuhle, 10/3/2003.

Photo 216. Picture at ca. 2810 m a.s.l., ca. 140 m above the talweg and the gravel floor (C), taken from the orographic right flank of the Dudh Koshi Nadi N of the Toktok settlement (27°45′35″ N 86°42′57″ E; Figure 4, Photo 216), facing W, showing a classic roche moutonnée (h) on the orographic right valley flank. Part of it is covered and surrounded by a ground moraine cover (0) containing far-travelled erratics of tourmaline granite, superimposed on outcropping Lower Tibetan grey mica gneiss (6b). Glaciofluvial polishings and glacier striae are still preserved on the gneiss surface of the roche moutonnée. These characteristic forms occur on the marginal rock faces which, due to flushing, have only recently been cleared of the loamy ground moraine cover. Analogue photo M. Kuhle, 10/3/2003.

Photo 217. Picture taken at ca. 2790 m a.s.l., ca. 150 m above the talweg of the Dudh Koshi Nadi N of the Toktok settlement (27°45′35″ N 86°42′57″ E; Figure 4, Photo 216), facing W, showing a classic roche moutonnée (h) on the orographic right valley flank. Part of it is covered and surrounded by a ground moraine cover (n) containing far-travelled erratics of tourmaline granite, superimposed on outcropping Lower Tibetan grey mica gneiss (6b). Glaciofluvial polishings and glacier striae are still preserved on the gneiss surface of the roche moutonnée. These characteristic forms occur on the marginal rock faces which, due to flushing, have only recently been cleared of the loamy ground moraine cover. Analogue photo M. Kuhle, 10/3/2003.
Photo 220. Picture taken at ca. 2630 m a.s.l., ca. 25 m above the talweg running in a glacial gorge (\( s \)), from the orographic right valley side (27°44'23" N/86°43'27" E; Figure 4, Photo 220) with the Thado Koshi Gaon settlement, facing ENE up the Thado Koshi Khola. Below the ca. 5800 m-high mountain at the valley head, a cirque-like polish floor is situated (\( s \)) from where the Würmian Thado Koshi glacier – as a left side valley component of the Dudh Koshi parent glacier – has started. (\( n \)) is ground moraine on the basal valley slopes, in many places covered by debris cones and fans (\( w \)) as well as angular boulders of rock fall (\( h \)) reaching the size of a house (for scale see the 2 1/2-storied house in front of it). The rock falls are crumblings which have taken place since the deglaciation up to nowadays. In many places their break-out scars (\( . \)) have damaged the glacigenic abrasion roundings (\( . \)), some of which have still been preserved on the boulders of the rock falls, so that these show a one-sided rounding with the old surface (e.g. on the right above\( . \) on top). Despite the flank abrasions (\( . \)), the valley shows a gorge-like V-profile; only toward below near to the talweg its end is trough-shaped (below\( . \) black). Accordingly, it can altogether be systematized as a gorge-like trough (Kuhle, 1982). Analogue photo M. Kuhle, 10/3/2003.

Photo 219. Taken from the orographic left flank of the Dudh Koshi Nadi at 2680 m a.s.l. (27°44'25" N/86°43'25" E; Figure 4, Photo 219) close to the Dukdingma settlement, facing SSE down-valley. The picture shows one of three parts of pothole forms (\( s \)); it is ca. 3 m in diameter (person for scale), and is situated on a rock ledge in the bedrock gneiss in the steep face of a subglacial gorge stretch, ca. 50 m above the current Dudh Koshi river. Into the surface of the pothole, which is still smooth, one has engraved “Om mani padme hum” with letters in size of decimeters to meters. Analogue photo M. Kuhle, 10/3/2003.

Photo 221. View taken at ca. 2540 m a.s.l., ca. 30 m above the talweg (below\( \square \) white) of the Dudh Koshi Nadi from the orographic left valley side (27°42'58" N/86°43'29" E; Figure 4, Photo 221), ca. 0.8 km S of the Thado Koshi Gaon settlement, facing SSW down-valley into the orographic right valley flank. (\( . \)) are High Würmian to early Late Glacial (Stages 0 and I, Table 1) glacigenic flank abrasions on the orographic right side. They are trough-like concavely polished out and have a ground moraine overlay (\( n \)). (II) is a Late Glacial remnant of end moraine of the Taglung Stage (Table 1; cf. Photo 227 II) black and white) are glaciolimnic sands compressed by the glacier tongue (\( n \)) of this stage (see Figure 87), which thus have become a pushed end moraine and can be addressed as accompanying remnants of a front moraine (Figure 11 II on the left below No. 73). (\( . \) and\( . \)) are remnants of a 5–6 m-thick glaciofluvial gravel overlay, covering the truncated surface of the push moraine (stratigraphic unconformity, discordance). Analogue photo M. Kuhle, 30/8/1982.
The maximum Ice Age (Würmian, Last Ice Age, LGM) glaciation of the Himalaya.

Photo 222. View taken at ca. 2720 m a.s.l., ca. 200 m above the talweg of the Dudh Koshi Nadi from the orographic left valley side (27°42'56" N 86°41'53" E, Figure 4, Photo 222, ca. 1 km S of the Thado Koshi Gaon settlement facing W up valley looking across the Thado Koshi Khola-junction (on the right of II). (III) is a ground moraine pediment, for the last time covered by a glacier tongue of the Dudh Koshi parent glacier during the Tadlung Stage (Table 1). (This tongue has come to an end in the area of the end moraine shown in Photo 221, cf. Figure 11 II on the left below No. 73 and Photo 227 III, on the left) is a remnant of a ground moraine pediment belonging to the Late Glacial Ghasa Stage (Table 1, II on the right) marks the W margin of the orographic left ground moraine pediment, which has to be classified as being from the High Würmian glacier cover (Stage II). (III) are two further High Würmian terrace-remnants of a ground moraine pediment at the corresponding level about 300-400 m above the current talweg of the main valley (III) (black) is the orographic right ground moraine pediment in the valley chamber of the Ghari settlement (IV white) is the ridge of the ground moraine pediment on which the Thado Koshi tributary glacier has joined the Dudh Koshi parent glacier. (V-VI) are glacigenic flank abrasions roughened by several postglacial rock crumblings. (V-VI) they have created valley cross-profiles with a typically concave course of the rock slopes so that trough-like valley cross-profiles have developed (VII). The upper polish lines run between 4000...5000 m a.u.s.l. (on the right) and 4000 m a.u.s.l. (on the left; cf. Figure 31). Analogue photo M. Kuhle, 9/3/2003.

Photo 223. Picture taken at ca. 2720 m a.s.l. from approx. 200 m above the talweg of the Dudh Koshi Nadi on the orographic left valley side (27°42'56" N 86°41'53" E, Figure 4, Photo 222. Photo 227 between 0 and 0 above), ca. 1.2 km S of the Thado Koshi Gaon settlement, facing E up-slope through an active erosion gully with spring erosion and slides (V) in a High-to Late Glacial (Stages 0-1; see Table 1) ground moraine pediment (0, 0 and 0 are 3-5 m-long (person for scale) in part round-edged (V) to edged polymict boulders; smaller boulders, which also 'swim' isolated from each other in a fine material matrix (see Figure 88) (on the right of II on the left), are sometimes faceted and a little better rounded. Analogue photo M. Kuhle, 8/4/2003.

Photo 224. Panorama from the orographic left flank of the Dudh Koshi Nadi, on the right side of the Handi Khola-exit in the Lukla settlement, taken at 2840 m a.s.l., ca. 840 m above the talweg of the main valley (0.1) 37°41'49" N 86°44'47" E; Figure 4, Panorama 224) from facing WNW (left margin) via NW with the 6611 m-high Karyolung (No. 16) in the background, via the 5885 m-high Nupla (No. 17) up to facing NNW (right margin) looking across the orographic right flank of the Dudh Koshi Nadi as far as up-valley, large in the foreground and 0–I) is the High Würmian ground moraine pedestal on which the Dudh Koshi glacier flowed during its greatest extension. It has been truncated by glaciofluvial activities and, during the Late Glacial Ghasa Stage (I, Table 1), covered by a partly thin gravel overlay on the orographic right side of the Handi Khola tributary glacier joining the main glacier. (V) is a corresponding remnant of a ground moraine pedestal on the orographic right main valley flank. (V) is the probably syngenetically, i.e. subglacially developed cut of the meltwater gorge through the ground moraine pedestal down to the outcropping rock ground (cf. Figure 54), shaped by the current Dudh Koshi river. (0 small in the background) are High Würmian remnants of ground moraine cover on the orographic right main valley flank. (0) are large, fresh crumblings currently destroying the rock roundings. (...) is the polish line running from ca. 4100 m a.s.l. (on the right) down to 3400 m (on the left) (see also Figures 32 and 33). Analogue photo M. Kuhle, 14/11/1982.
Photo 225. Picture taken from the orographic left flank of the Dudh Koshi Nadi, on the right side of the Handi Khola-exit in the Lukla settlement at ca. 2800 m a.s.l., approx. 800 m above the talweg of the Dudh Koshi Nadi (27° 46' 02" N/86° 44' 45" E; Figure 4, Photo 225), facing E, showing a 2 m-deep excavation exposure of ground moraine in the High Wiirmian ground moraine pedestal. The exposed moraine material \( (\bullet) \) consists of more or less round-edged and facetted augengneiss boulders up to extensions of 1.5 m \( (\triangle) \), embedded into a strongly condensed matrix, which is rich in clay and associated with edged, less metamorphic components of schist. Analogue photo M. Kuhle, 9/3/2003.

Photo 226. Panorama picture from the orographic left flank of the Dudh Koshi Nadi, on the right side of the Handi Khola-exit SW below the Lukla settlement at ca. 2770 m a.s.l., taken from ca. 770 m above the talweg of the main valley (below \( \circ \) small) (27° 46' 50" N/86° 44' 10" E; Figure 4, Panorama 226) facing SE (left margin) up the Handi Khola, via S (\( \odot \)) down the main valley and on to the orographic left lateral moraine of the Handi Khola glacier of the Late Glacial Ghasa Stage (I, Table 1), up to facing W into the orographic right main valley flank (right margin, background). This lateral moraine \( (I) \) is situated on the High Wiirmian surface of the ground moraine pedestal \( (\bigcirc) \) about 2700 m a.s.l. \( (\square) \) is the corresponding orographic right inner slope of the Handi Khola tributary glacier moraine of the Ghasa Stage (cf. Figure 89). \( (\odot) \) is an outcropping rock head, abraded and polished like a roche moutonnee. \( (\odot) \) marks a subglacially eroded fluvial cutting which since the deglaciation has undergone a further subaerial development. \( (\odot) \) are orographic left High Wiirmian flank abrasions the upper limit of which \( (\ldots) \) testifies to a glacier trim-line of the Handi Khola tributary glacier between 4000 and 3900 m a.s.l. \( (\ldots) \) was the contemporaneous surface of the Dudh Koshi parent glacier between \( (\ldots) \) on the right 2280 and 2700 m a.s.l. \( (\ldots) \) on the left \( (\ldots) \) Figure 54 \( (\bullet) \) small \( (\circ) \) is a ground moraine cover and \( (\bigcirc) \) a truncated spur on the orographic right main valley flank. Analogue photo M. Kuhle, 9/3/2003.
... during the Wu¨rmian period (Stage 0). (0) are further remnants of the ground moraine pedestal. It has been – and still is – cut by the Dudh Koshi river(s) (Fig. 6) and debris flow fans of dislocated moraine, small rock avalanches and crumblings, laid down on the surface of the ground moraine pedestal since the deglaciation. (C) are glaciolimnic deposits in the area of a Late High Wu¨rmian to Early Late Glacial (Stages 0–I) orographic left lateral sander, sedimented into a lateral valley between valley glaciers and valley flank (Figure 90). (C), (T) are glaciolimnic deposits, roughened by several postglacial rock crumblings. (C) are debris cones and debris flow fans of dislocated moraine, small rock avalanches and crumblings, cut down by the Dudh Koshi river (Fig. 6). (T) are remnants of a ground moraine pedestal, reshaped by the Dudh Koshi river (Fig. 6). (2) mark remnants of a ground moraine cover, left behind by the High Wu¨rmian valley glacier on the left valley flank. In places they alternate with glaciolimnic deposits of an early Late Glacial (Stages 0–I) on the slope surface. (C) are glacigenic flank abrasions, roughened by several postglacial rock crumblings (Fig. 52). The upper limits of the abrasions provide evidence of a course of the glacier trim-line running from ca. 4000 m a.s.l. (from the left in the background (Figure 52), via 3600 m (second ... from the left) in the middleground. At (C) in the background, the valley cross-profiles are most trough-like (Figures 52 and 53). (C) is a debris flow fan with boulders of rock avalanches, cut down by the ground moraine pedestal. (0) mark remnants of a ground moraine pedestal, left behind by the High Wu¨rmian glacier – as the lowest tributary glacier – was connected with the Dudh Koshi parent glacier (Figure 4 and 11 on the right below No. 16). (C) are remnants of glaciolimnic deposits of lateral formation (Figure 90), deposited during a High Wu¨rmian (Stage 0) to early Late Glacial (Ghasa Stage I) lateral valley between the glacier and the orographic left valley flank (Photo 227). (0) is the lowest ice margin position of the Late Glacial Dudh Koshi Nadi during the Taglung Stage, situated at ca. 2500 m a.s.l. (Photo 221). Analogue photo M. Kuhle, 2/9/1982.

Photo 230. Picture taken at ca. 2470 m a.s.l. N, above the Surke settlement (0–I), from the orographic left flank of the Dudh Koshi Nadi, ca. 670 m above the talweg of the Dudh Koshi Nadi (27° 20’32” N/86° 44’45” E; Figure 4, Photo 230), facing NNW down the main valley (0–I and 0) are remnants of a ground moraine pedestal the core of which is of a High Würmian age (Stage 0). During the first Late Glacial Stage (Ghasa Stage I, Table 1) it was reshaped by the valley glacier tongue – coming to an end somewhat down-valley – and fluvially undercut during the postglacial period. (i) are remnants of ground moraine (Figure 94), (on the left above), situated at an altitude of about 2050 m (on the left above), is of a High Glacial age (Figure 93), (0 and 0) are glacigenically remodeled triangular-shaped slopes; (0), (0), (0) are flank abrasions damaged by crumblings; (...) shows upper limits of abrasion, which, according to their bands similar to polish cavettos, are recognizable as indicators of the highest past glacier level (... on the left, cf. Figure 54). Analogue photo M. Kuhle, 9/3/2003.

Photo 232. Picture at ca. 1800 m a.s.l. in the junction area of the Khari Khola and the Dudh Koshi Nadi, from the orographic left flanks of the two valleys, taken from ca. 250 m above the talweg of the Dudh Koshi Nadi (27° 36’47” N/86° 42’15” E; Figure 4, Photo 232), facing N up the main valley (0) are ground moraine remnants, the thickness of which at a corresponding relief small-scale reaches one decametre (black), but mostly only a few metres (white); (0) are round-edged boulders, 1–2 m in size. (0), (0), (0) are glacigenic flank abrasions in the mica garnet gneiss (background) and mica schist (foreground), roughened by crumblings; due to the gorge fog, at this altitude the break-out scars have been covered with grasses and lichens within a few years so that they cannot be distinguished by their colour. (0) is a truncated spur. The outcropping rock banks incline with 27° to the NW so that the Dudh Koshi Nadi has an obsequent course; due to the subsequent small tributary valleys and glacial gorges, developed in the minor-resistant mica schist, the abraded, convex rock spurs protrude (0); the Dudh Koshi river completely covering the bottom of the glacial gorge (0) (...) marks the High Würmian (Stage I) glacier trim-lines, running from ca. 2700 m (the two ... from the right) (Figure 54) down to ca. 2300 m a.s.l. (...) on the very left. Analogue photo M. Kuhle, 27/8/1982.

Photo 231. Panorama taken from N of the Chutok La (pass) at ca. 2790 m a.s.l. from the orographic left flank of the Dudh Koshi Nadi, ca. 1000 m above the talweg of the Dudh Koshi Nadi (27° 39’45” N/86° 43’40” E; Figure 4, Panorama 231), facing W (left margin) into the orographic right flank of the Lumding Khola, via facing NW on to the 6611 m-high Karyolung (No. 16), via facing NW on to the 5885 m-high Nupla (No. 17), facing N up the Dudh Koshi Nadi on to the 5761 m-high Khumbui Yul Lha (No. 74), up to NE (right margin) into the orographic left flank of the main valley. (0) are remnants of ground moraine the thickness of which increases from the valley flanks (Figure 94) down to the valley bottom, forming ground moraine pedestals (0 and 0 below) up to (0). (0 and 0) are remnants of ground moraine pedestal, overgrown and modified by the early Late Glacial Dudh Koshi glacier as late as Stage I. Below (0), the lateral moraines of the Hindu Khola glacier are situated, overlying the High Würmian ground moraine pedestal (0 above) (Figure 11, far below No. 74 I; Photo 226). (0 and 0) are glacigenic to glaciolimnic sands, heaped up in an orographic left lateral valley (Figure 90), (0) are glacigenically triangular-shaped slopes developed from truncated spurs. (0), (0) mark flank abrasions (0), which have been damaged by crumblings; their upper limit proves the High Würmian glacier trim-line (...) it runs on the left below No. 74 at about 4200–4000 m (Figure 52), below No. 17 and on the right below No. 74 at about 3900–360000 m (Figure 53), on the very right and below, below No. 16, at about 2800 m, and below No. 16 above up to below on the very left in the Lumding Khola, from ca. 3600 down to 2700 m a.s.l. Analogue photo M. Kuhle, 9/3/2003.
Photo 233. Panorama taken at ca. 1700 m a.s.l. from the Jubing hamlet down-valley of the Khari-junction (white) and up the confluence of the Deku Khola and the Dudh Koshi Nadi, from the orographic left flanks of the main valley from ca. 300 m above the talweg of the Dudh Koshi Nadi (27°16' 27" N, 86° 41' 95" E; Figure 4, Photo 233) from facing WNW (left margin) via facing up the main valley, up to facing NE (right margin) (black) is the Dudh Koshi river flowing out of a subglacially developed gorge-stretch (white). (white) is an orographic left lateral kame, which from the Khari Khola has been accumulated against the down-melting tongue of the Dudh Koshi glacier. (black) are metre- to decametre-thick remnants of ground moraine, mainly situated on the flatter orographic left valley slopes, (black) indicates an erosion gully, cutting and exposing a ground moraine head. (white) are up to 3 m-long gneiss boulders, which, isolated from each other, stick in a clayey matrix. (black) are rock roundings on the flanks created by glacigenic abrasions. Since the deglaciation they have been roughened by crumblings (white). Due to the monsoon-specific climate, nearly all the damages by crumblings are covered with grass. (black) is a meltwater tube subglacially developed between the valley glacier flank and the valley face. (white) marks the Würmian (stage II) glacier trim-line approx. reconstructed at ca. 2500 m (second from the left) down to ca. 2250 m a.s.l. (second from the very left) (Figure 55). Analogue photo M. Kuhle, 27/8/1982.
deposition. Their hydrothermal decay in the bedrock must have been less or the process of displacement in the course of the glacier transport was different, etc. Already the difference with regard to the condition of the boulders at one and the same place disproves the possibility of age determination of moraines by the dating of boulder surfaces (Section 3.8.2). Additionally, in the research area fresh local boulders of rock falls have been observed on moraines, upon which the one-sided past rounding of the rock face from which they have fallen, has been preserved (e.g. Photo 220). The age which can be determined by the rounding, is the integral age of the surface of the rock face before the rock fall; whilst the age which is determinable by the other boulder faces, is that of the rock avalanche. However, none of these age data have to do with the age of the moraine.

5.3. The snow-line depression as climate indicator (Figure 11)

The cirque level and the Würmian (Stage 0) height of the snow-line depression as climate indicator data have to do with the age of the moraine. However, none of these age determinable by the other boulder faces, is that of the rock avalanche. Checking this snow-line calculation according to a method which considers the medium altitude of the crest fringe of the catchment area

\[
S_{\text{depr}} = (\text{pha} - ti)/2 + ti
\]  

(\(S_{\text{depr}}\) = equilibrium line depression (ELA-depression), \(\text{tp}\) = recent terminus of the glacier tongue; \(ti\) = past terminus of the glacier tongue)

500 = 4000; 4000:2 = 2000. Accordingly, the ELA-depression in the S-slope of the Khumbakarna Himal was 2000 m.

The medium lowest current glacier terminus in the catchment area of the Würmian Arun glacier (\(tp\), that of the Lower Barun glacier, is situated at 4500 m a.s.l. (\(tp = 4500\)) (Section 2.1); the Würmian glacier terminus of the Arun glacier (\(ti\)) lay at ca. 500 (450) m a.s.l. (\(ti = 500\)) (Sections 2.4.5 and 2.4.7). 4500 = 500 = 4000; 4000:2 = 2000. Accordingly, the ELA-depression in the S-slope of the Khumbakarna Himal was 2000 m.

The medium lowest current glacier terminus in the catchment area of the Würmian Dudh Koshi glacier (\(tp\), like that of the large Ngozumpa glacier, is located at 4600 m a.s.l. (\(tp = 4600\)) (Figures 3 and 19) (Section 3.6); the Würmian glacier terminus of the Dudh Koshi glacier (\(ti\)) lay at ca. 900 m a.s.l. (\(ti = 900\)) (Section 3.9.2). 4600 – 900 = 3700; 3700:2 = 1850. Accordingly, the ELA-depression in the S-slope of the Khumbu Himal was 1850 m. In correspondence, the ELA-depressions of the Late Glacial glacier Stages II, III and IV, which in the Dudh Koshi Nadi, i.e. Ngozumpa- or Nangpo Tsangpo Drangka were located at 1800(I),2500(II),2750(III) and about 3300(IV) m a.s.l., amounted to 1400, 1050, 925 and 650 m.

At a methodically different calculation of the snow-line, the areal relation of glacier feeding- to ablation area has to be considered. Experience has shown that in the high mountain valley area concerned it is ca. 2:1. This corresponds to an AAR (accumulation area ratio) of 0.66. In the relief of the Khumbu Himal described, a High Würmian ELA-depression of only 1200 m (see Figure 17) at an AAR of 0.66, already leads to an ice margin at 610 m a.s.l. in the lower Dudh Koshi Nadi (see Figure 17). That is a 300 m lesser altitude above sea-level than the ice margin at 900 m a.s.l., which has been made empirically probable (Sections 5.1 and 3.9.2).
the Würmian Ice Age (Stage 0) would have dropped by ca. 8 (8.15) °C; at a more arid gradient of 0.6 °C/100 m by ca. 10 (9.78) °C. The snow-line altitudes and ELA-depressions of the Late Glacial-, Neoglacial- to Historical glacier stages are presented in Tables 1, 3 and 4 and summarized in Section 5.2.

Acknowledgements

The author expresses his thanks to his co-workers at the Geographical Institute, University of Göttingen, who helped to complete the research results presented in this study, especially Dipl. Geogr. M. Wagner and cartograph A. Flemnitz for drawing the basics of the maps and Mr. Wagner for his assistance with regard to the preparation of the photos. For the scanning of the maps in Figure 2 I thank my colleague Priv. Doz. Dr. J. Ehlers (Hamburg). I am grateful to Mrs. J. Jörgens for the translation of the manuscript and to my colleague Dr. J.A. Hellen (Newcastle upon Tyne) for his conscientious and patient reworking of the English version. Thanks are also due to the Deutsche Forschungsgemeinschaft (DFG) which supported my 3 1/2-months Khumbu expedition.
